Abstract: *Septoria* represents a genus of plant pathogenic fungi with a wide geographic distribution, commonly associated with leaf spots and stem cankers of a broad range of plant hosts. A major aim of this study was to resolve the phylogenetic generic limits of *Septoria*, *Stagonospora*, and other related genera such as *Sphaerulina*, *Phaeosphaeria* and *Phaeoseptoria* using sequences of the partial 28S nuclear ribosomal RNA and RPB2 genes of a large set of isolates. Based on these results *Septoria* is shown to be a distinct genus in the *Mycosphaerellaceae*, which has mycosphaerella-like sexual morphs. Several septoria-like species are now accommodated in *Sphaerulina*, a genus previously linked to this complex. *Phaeosphaeria* (based on *P. oryzae*) is shown to be congeneric with *Phaeoseptoria* (based on *P. papayae*), which is reduced to synonymy under the former. *Depazea nodorum* (causal agent of nodorum blotch of cereals) and *Septoria avenae* (causal agent of avenae blotch of barley and rye) are placed in a new genus, *Parastagonospora*, which is shown to be distinct from *Stagonospora* (based on *S. paludosa*) and *Phaeosphaeria*. Partial nucleotide sequence data for five gene loci, ITS, LSU, EF-1α, RPB2 and Btub were generated for all of these isolates. A total of 47 clades or genera were resolved, leading to the introduction of 14 new genera, 36 new species, and 19 new combinations.

Key words: Capnodiales, Multi-Locus Sequence Typing (MLST), Mycosphaerella, Mycosphaerellaceae, Phaeoseptoria, Phaeosphaeria, Phaeosphaeriaceae, Pleosporales, Septoria, Sphaerulina, Stagonospora, systematics.

doi:10.3114/sim0017. Hard copy: June 2013.

INTRODUCTION

Fungal species belonging to *Septoria* are among the most common and widespread leaf-spotting fungi worldwide. *Septoria* Sacc. (*Mycosphaerella*, *Capnodiales*, *Dothideomycetes*) is based on *Septoria cytisi*, which was first described by Desmazières (1847) as a pathogen of *Cytisus laburnum* (= *Laburnum anagyroides*).

The genus *Septoria* is extremely large, and during the past 150 years more than 2000 taxa have been ascribed to this asexual genus (Verkley & Priest 2000, Verkley et al. 2004). Presently, *Septoria* s.l. represents a polyphyletic assembly of genera that cluster mostly in the *Mycosphaerellaceae* (a family incorporating many plant pathogenic coelomycetes), although fungi with septoria-like morphology have also evolved outside this family

(Crous *et al.* 2009a, c). Although many species of *Septoria* have mycosphaerella-like sexual states, the name *Mycosphaerella* does not apply to them, and should not be used in this context.

Following a proposal accepted by the International Code of Nomenclature for algae, fungi and plants (ICN), the generic name *Septoria* Sacc. was conserved over the older synonym *Septaria* Fr. (original spelling). The arguments preceding the typification of *Septoria* and subsequent proposals for name conservation by Wakefield (1940), Rogers (1949) and Donk (1964) between *Septoria sensu* Saccardo or *Septaria* Fries were various. In the end the committee for fungi appointed by the ICN followed the recommendation of Donk (1964), and decided on *Septoria* Sacc. over *Septaria* Fr., arguing that *Septoria* Sacc. had already been in prevalent use for many years, and should therefore be accepted as the correct name.

After examining several herbarium specimens of *S. cytisi*, Sutton (1980) circumscribed *Septoria* as follows: *Mycelium* immersed, branched, septate, pale brown. *Conidiomata* pycnidial, immersed, separate or aggregated (but not confluent), globose, papillate (or not), brown, thin-walled of pale brown *textura angularis*, often with a smaller-celled inner layer, somewhat darker and more thick-walled around the ostiole. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* holoblastic, either determinate or indeterminate, with a limited number of sympodial proliferations. Each locus has a broad, flat, unthickened scar, discrete, hyaline, smooth, ampulliform, doliform or lageniform to short cylindrical. *Conidia* hyaline, multiseptate, filiform, smooth and either continuous or constricted at septa. Later work by Constantinescu (1984), Sutton & Pascoe (1987, 1989) and Farr (1991, 1992) augmented Sutton's previous generic circumscription by also including species with sympodial, enteroblastic and percurrent conidial proliferation. Furthermore, based on similarities in conidiomatal development, von Arx (1983) and Braun (1995) adopted an even wider concept of *Septoria* that included the acervular forms normally accommodated in *Phloeospora*.

Morphological traits in *Septoria* are generally conserved, and specific morphological characters by which to describe and identify *Septoria* and septoria-like species are limited. This lack of specific morphological characters caused *Septoria* taxonomy to be largely dependent on associated host data, leading to many of the described species only being identifiable by host plant, and by variation in informative supplementary characters like conidial length, width and septation (Jørstad 1965, 1967, Sutton 1980). Of these supplementary characters, conidial width appears to be the most stable (i.e. it shows the least amount of intraspecific variation) and in most *Septoria* species, intraspecific conidial width rarely varies more than 1 µm (Priest 2006).

This reliance on host data in *Septoria* taxonomy is far from perfect, and should be avoided for identification purposes (see Verkley *et al.* 2013, this volume). Extensive host inoculation experiments by Beach (1919) and Teterevnikova-Babayan (1987) have shown that identification of *Septoria* spp. by host specificity alone is error prone because many *Septoria* species are not restricted to a single specific host (i.e. several taxa have broader host ranges). *Septoria* species like *S. lactucicola* and *S. lycopersici* can not only infect multiple plant species within the same genus, but can also infect plants belonging to closely allied families and genera. In contrast to this, morphologically well distinguishable *Septoria* species can also parasitise the same hosts (e.g. multiple distinct *Septoria* species can be found on both *Chrysanthemum* and *Rubus* hosts) (Demaree & Wilcox 1943, Punithalingam 1976, Shin & Sameva 2004). Because host specificity has been

one of the main criteria used for describing new, morphologically indistinguishable *Septoria* species over the past 150 years, one can expect that a certain number of described taxa are in fact synonyms of species from related hosts.

***Septoria* and septoria-like genera in the molecular era**

Although it had previously been speculated by Sutton (1980) that *Septoria* was in fact polyphyletic, definitive proof of this hypothesis awaited the introduction of molecular techniques. Cunfer & Ueng (1999) were the first to use rDNA sequence data of the internal transcribed spacer region (ITS) to postulate that *Zymoseptoria tritici* (then known as *Septoria tritici*) and several *Stagonospora* spp. (a morphologically similar genus, previously linked to *Septoria*) actually belonged to two distinct genera. Verkley *et al.* (2004) extended this study by employing a combination of 28S nrDNA (LSU) and ITS data to prove that *Septoria* was in fact both poly- and paraphyletic. Their work showed that septoria-like species such as *Z. tritici* and *Z. passerinii* were more closely related to *Ramularia* than to the majority of the other *Septoria* species used in their datasets.

Feau *et al.* (2006) were the first to use a multi-locus polyphasic sequencing approach to reliably identify *Septoria* spp. Besides ITS and LSU sequence data, they also used β-tubulin (Btub) sequence data to separate closely related species into distinct monophyletic groups that frequently correlated with their respective host families. These results supported the approach of using multi-gene sequence data for studying a large collection of *Septoria* strains at species level.

Septoria s. str. was finally demarcated when Quaedvlieg *et al.* (2011) managed to obtain both ITS and LSU sequence data from *S. cytisi* herbarium specimens. Phylogenetic analysis of the obtained *S. cytisi* LSU sequence data clearly proved that *Z. tritici* and *Z. passerinii* [as previously indicated by Cunfer & Ueng (1999) and Verkley *et al.* (2004)] did not belong to *Septoria s. str.*, but in fact belonged to a separate genus, closely related to *Ramularia*. These two species were subsequently split off from *Septoria* and placed in a new genus, *Zymoseptoria* (named for the yeast-like state produced in culture). Since the initial *Zymoseptoria* paper, five additional species from members of Poaceae have been described in this genus (Crous *et al.* 2012a, Stukenbrock *et al.* 2012).

***Septoria*-like asexual genera**

Since the description of *Septoria* by Desmazières (1847), several additional septoria-like genera (pycnidial/acervular/stromatic conidioma with filiform conidia) have been described which could be mistaken for *Septoria s. str.*

The two economically most important septoria-like genera are probably *Zymoseptoria* (sexual morph mycosphaerella-like) and *Parastagonospora* (sexual morph phaeosphaeria-like; see below). Both of these genera are pathogenic on Poaceae (grasses) and are directly or indirectly responsible for significant annual crop losses worldwide on cereals such as barley and wheat (Eyal *et al.* 1987). Quaedvlieg *et al.* (2011) determined that *Zymoseptoria* formed a distinct clade in the Mycosphaerellaceae, while *Stagonospora* was found to cluster in the Phaeosphaeriaceae within the Pleosporales, near other genera like *Phoma* and *Phaeosphaeria* (Cunfer & Ueng 1999, Solomon *et al.* 2006) which contain important plant pathogens. However, besides *Zymoseptoria* and *Parastagonospora* there are many other, lesser-known septoria-like genera awaiting

elucidation. The goal of the present study is therefore to conduct an in-depth morphological and molecular analysis of these septoria-like genera, and resolve the affinities of *Stagonospora* and its purported sexual morph, *Phaeosphaeria*. To this end a collection of 370 *Septoria* and septoria-like isolates (Table 1) were subjected to morphological examination and multi-gene DNA analyses.

MATERIALS AND METHODS

Isolates

Symptomatic leaves were incubated in moist chambers for up to 1 wk to enhance sporulation before single conidial colonies were established on 2 % malt extract agar (MEA) (Crous *et al.* 2009d). Leaf spots bearing ascocarps were soaked in water for approximately 2 h, after which they were attached to the inner surface of Petri dish lids over plates containing MEA. Ascospore germination patterns were examined after 24 h, and single ascospore cultures established as described previously (Crous *et al.* 1991, Crous 1998). Colonies were sub-cultured onto synthetic nutrient-poor agar (SNA) containing sterile *Hordeum vulgare* (barley) and *Urtica dioica* (stinging nettle) stems, potato-dextrose agar (PDA), oatmeal agar (OA), and MEA (Crous *et al.* 2009d), and incubated at 25 °C under continuous near-ultraviolet light to promote sporulation. Isolates were also obtained from the culture collections of the CBS-KNAW Fungal Biodiversity Centre (CBS) in Utrecht, and the working collection of Pedro Crous (CPC). Reference strains were deposited CBS (Table 1).

DNA extraction, amplification and sequencing

Genomic DNA was extracted from fungal mycelium growing on MEA, using the UltraClean® Microbial DNA Isolation Kit (Mo Bio Laboratories, Inc., Solana Beach, CA, USA). Strains (Table 1) were screened for five loci (β -tubulin (Btub), internal transcribed spacer (ITS), Translation elongation factor 1-alpha (EF-1 α) 28S nrDNA (LSU) and RNA polymerase II second largest subunit (RPB2) using the primer sets listed in Table 2. The PCR amplifications were performed in a total volume of 12.5 μ L solution containing 10–20 ng of template DNA, 1 \times PCR buffer, 0.7 μ L DMSO (99.9 %), 2 mM MgCl₂, 0.4 μ M of each primer, 25 μ M of each dNTP and 1.0 U Taq DNA polymerase (GoTaq, Promega). PCR amplification conditions were set as follows: an initial denaturation temperature of 96 °C for 2 min, followed by 40 cycles of denaturation temperature of 96 °C for 45 s, primer annealing at the temperature stipulated in Table 2, primer extension at 72 °C for 90 s and a final extension step at 72 °C for 2 min. The resulting fragments were sequenced using the PCR primers together with a BigDye Terminator Cycle Sequencing Kit v. 3.1 (Applied Biosystems, Foster City, CA). Sequencing reactions were performed as described by Cheewangkoon *et al.* (2008). All novel sequences were deposited in NCBI's GenBank database and alignments and phylogenetic trees in TreeBASE.

Phylogenetic analyses

A basic alignment of the obtained sequence data was first done using MAFFT v. 7 [<http://mafft.cbrc.jp/alignment/server/index.html>] (Katoh *et al.* 2002) and if necessary, manually improved in BioEdit v. 7.0.5.2 (Hall 1999). To check the congruency of the RPB2 and LSU dataset, a 70 % neighbour-joining (NJ) reciprocal bootstrap

method with maximum likelihood distance was performed (Mason-Gamer & Kellogg 1996, Lombard *et al.* 2010). Bayesian analyses (critical value for the topological convergence diagnostic set to 0.01) were performed on the concatenated loci using MrBayes v. 3.2.1 (Huelsenbeck & Ronquist 2001) as described by Crous *et al.* (2006) using nucleotide substitution models that were selected using MrModeltest v.2.3 (Table 3) (Nylander 2004). In order to keep the trees manageable for publication, two separate Bayesian trees were run. The first tree was run with all the *Septoria* and septoria-like isolates that either belonged to, or were more closely related to the *Mycosphaerellaceae* (Fig. 1) while the second tree contained all the septoria-like isolates either belonging to, or being more closely related to the *Phaeosphaeriaceae* (Fig. 2). *Parastagonospora nodorum* (CBS 259.49) was used as outgroup for the *Mycosphaerellaceae* dataset, while *Dothistroma pini* (CBS 121005) was used as outgroup for the *Phaeosphaeriaceae* dataset. As the novel genera and species described in this study were already clearly distinguishable in the LSU/RPB2 trees, the ITS, EF-1 α and Btub sequence data of these isolates were deposited in GenBank without their subsequent trees being published in this paper.

Taxonomy

Taxonomic descriptions were based on isolates sporulating in culture. Diseased leaf tissue was viewed under a Zeiss V20 Discovery stereo-microscope, while a Zeiss Axio Imager 2 light microscope with differential interference contrast (DIC) illumination and an AxioCam MRc5 camera with Zen software was used to capture morphological structures. Adobe Photoshop CS3 was used for the final editing of acquired images and photographic preparations. For measurements, 30–50 replicates of all relevant morphological features were made at $\times 1000$ magnification. Colony characters and pigment production were noted after 2–4 wk of growth on MEA, PDA and OA (Crous *et al.* 2009d) incubated at 25 °C in the dark. Colony colours (surface and reverse) were rated according to the colour charts of Rayner (1970).

RESULTS

DNA sequencing and phylogenetic analysis

The RPB2 and LSU sequence datasets did not show any conflicts in both the *Mycosphaerellaceae* and *Phaeosphaeriaceae* tree topologies for the 70 % reciprocal bootstrap trees, allowing us to combine them in the multigene analyses. For the *Mycosphaerellaceae* tree, the gene boundaries were: 1–327 bp for RPB2 and 332–1120 bp for LSU. For the *Phaeosphaeriaceae* tree (Fig. 2), the gene boundaries were 1–777 bp for LSU and 782–1108 bp for RPB2. During the generation of the *Mycosphaerellaceae* tree (Fig. 1), a total of 57 048 trees were sampled out of the generated 76 062 trees (75 %). During the generation of the *Phaeosphaeriaceae* tree (Fig. 2), a total of 2844 trees were sampled out of the generated 3792 trees (75 %).

Taxonomy

A total of 347 isolates representing 170 species were subjected to DNA analysis and morphological comparison. Phylogenetic analyses based on the LSU and RPB2 genes resolved a total of 47 clades of

Table 3. Amplification success, phylogenetic data and the substitution models used in the phylogenetic analysis, per locus.

Locus	RPB2	LSU
Amplification success (%)	99.20 %	100 %
Number of characters	327	792
Unique site patterns	197	216
Substitution model used	GTR-I-gamma	GTR-I-gamma
Number of generations (1000×)		2575
Total number of trees (n)		5152
Sampled trees (n)		3864

which 26 contained species belonging to the *Septoria* (-like) complex. These 47 resolved clades belong to a multitude of different families within the *Dothidiomycetes* ranging from the *Mycosphaerellaceae* in the *Capnodiales* to the *Lentitheciaceae* in the *Pleosporales*. It is still unclear within the *Dothidiomycetes* where the phylogenetic family borders are located, or even how many phylogenetically substainable families there actually are. The family annotation in the phylogenetic trees (Figs 1, 2) is therefore based on the closest LSU neighbour that was available in GenBank, with clades treated as *incertae sedis* if no closer relationship than 97 % could be found.

Septoria and septoria-like genera

In addition to *Septoria* s. str., numerous septoria-like genera (pycnidial/acervular/stromatic conidioma with filiform conidia) have since been described. Although the majority of these have no ex-type culture available for DNA analysis, many have type material deposited in herbaria, which were available for morphological examination. A summary of these genera is provided below.

Pycnidial forms

Cytostagonospora Bubák, Ann. Mycol. 14: 150. 1916. Fig. 3.

Mycelium immersed, dark brown, branched, septate. *Conidiomata* pycnidial, amphigenous, separate, globose, dark brown to black, immersed, unilocular, thick-walled, clypeate; walls of dark brown, thick-walled *textura angularis* to *textura globulosa*, becoming hyaline towards the conidiogenous region, extending in the upper part to become a circular clypeus of similar thickness to the wall. *Ostiole* central, circular, papillate to shortly rostrate, depressed, situated immersed within the clypeus. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* holoblastic, determinate, discrete, lageniform, hyaline, smooth, formed from the inner cells of the pycnidial wall. *Conidia* hyaline, 0–2-euseptate, not constricted at septa, base truncate, apex obtuse, thin-walled, eguttulate, smooth, filiform, often curved (Sutton 1980).

Type species: *C. photiniicola* Bubák, Ann. Mycol. 14(3–4): 150. 1916.

Notes: Von Arx (1983) and Sutton (1980) disagreed about the link of *Cytostagonospora* to *Septoria*. Von Arx treated it as a synonym of *Septoria*, while Sutton retained it as a separate genus.

Dearnessia Bubák, Hedwigia 58: 25. 1916.

Mycelium hyaline to brown, branched, septate. *Conidiomata* pycnidial, amphigenous, separate, globose, immersed, brown; wall of thin-walled *textura angularis*. *Ostiole* central, circular, papillate. *Setae* ostiolar, approximately straight, unbranched, tapered towards apex, dark brown, smooth, thin-walled, septate. *Conidiogenous cells* holoblastic, determinate, discrete, doliform to ampulliform, hyaline, smooth and formed from the inner layer of the pycnidial wall. *Conidia* cylindrical to irregular, hyaline, 1–multi-transversely euseptate, rarely with 1–2 longitudinal eusepta, continuous or constricted, often tapered at the apex, base truncate, thin-walled, smooth, guttulate or not (Sutton 1980).

Type species: *D. apocyni* Bubák, Hedwigia 58: 25. 1916.

Dearnessia apocyni Bubák, Hedwigia 58: 25. 1916. Figs 4, 5.

Leaf spots amphigenous, irregular, feathery to angular, dark brown, 3–6 mm diam, surrounded by a wide chlorotic zone up to 3 mm diam. *Conidiomata* epiphyllous, pycnidial, erumpent, up to 150 µm diam, with central ostiole; wall of 3–6 layers of brown *textura angularis*. *Conidiogenous cells* doliform, globose to subcylindrical, hyaline, smooth, thin-walled, mode of proliferation obscure, 5–10 × 4–6 µm. *Conidia* hyaline, smooth, subcylindrical to obclavate, apex obtuse, base truncate to subobtuse, straight to irregular (lateral swellings?), 1–4-septate, 16–33 × 5–8 µm.

Specimen examined: Canada, Ontario, London, on leaves of *Apocynum androsaemifolium* (Apocynaceae), 11 Aug. 1910, J. Dearness, holotype F43227.

Notes: Because the specimen is in poor condition, no definite conclusion could be reached about its potential relationships. However, *D. apocyni* does appear septoria-like in general morphology.

Jahniella Petr., Ann. Mycol. 18: 123. 1921. [1920]. Figs 6, 7.

Mycelium branched, immersed, septate, brown. *Conidiomata* pycnidial, superficial on epidermis, immersed, separate, globose, papillate, dark brown, thick-walled, sclerenchymatic; wall consisting of an outer layer of dark brown, thick-walled *textura angularis*, a middle layer of 8 cells thick, of hyaline to pale brown, thick-walled cells, and an inner layer of thin-walled, hyaline, irregular cells. *Ostiole* single, circular, with a distinct channel and hyaline

Fig. 2. A Bayesian 50 % majority rule RPB2/LSU consensus tree containing all *Septoria* and septoria-like taxa available at the CBS, which cluster in or near the Phaeosphaeriaceae. Bayesian posterior probabilities support values for the respective nodes are displayed in the tree. A stop rule (set to 0.01) for the critical value for the topological convergence diagnostic was used for the Bayesian analysis. The tree was rooted to *Dothistroma pini* (CBS 121005). The scalebar indicates 0.01 expected changes per site.

Fig. 2. (Continued).

periphysoid cells. Conidiophores reduced to conidiogenous cells. Conidiogenous cells holoblastic, determinate, discrete, hyaline, ampulliform, lining the wall of the pycnidium. Conidia straight or slightly curved, hyaline, thin-walled, smooth, 3–4-euseptate, eguttulate, truncate at the base, slightly tapered to the apex (Sutton 1980).

Type species: *J. bohemica* Petr., Ann. Mycol. 18(4–6): 123. 1921. [1920]

Specimen examined: Czech Republic, Bohemia, on stems of *Scrophularia nodosa* (Scrophulariaceae), 18 Mar. 1916, J. Jahn, holotype K(M) 180917, slides ex BPI.

Note: The specimen correlates closely with the description provided by Sutton (1980), except that the conidiomata are superficial, not immersed in the epidermis.

Megaloseptoria Naumov, Morbi Plantarum 14: 144. 1925.
Figs 8, 9.

Mycelium immersed, branched, septate, brown. Conidiomata pycnidial, separate, globose, slightly papillate, dark brown to

black, superficial, sessile, often aggregated in groups, unilocular, thick-walled; wall of several cell layers of brown *textura angularis*, more darkly pigmented on the outside. Ostiole single, circular. Conidiophores hyaline, branched, septate (mainly at the base), smooth, straight or irregular, formed from the inner cells of the pycnidial wall. Conidiogenous cells enteroblastic, determinate, discrete or integrated, doliform, ampulliform or irregularly cylindrical, hyaline, smooth, collarette evident, channel wide, periclinal thickening present. Conidia hyaline to pale brown with several transverse eusepta, continuous, tapered near the obtuse apex and truncate base, thin-walled, smooth, cylindrical, straight or slightly curved, often with 2 guttules in each cell (Sutton 1980).

Type species: *M. mirabilis* Naumov, Morbi Plant. Script. Sect. Phytopath. Hort. Bot. Prince. USSR 14: 144. 1925.

Megaloseptoria mirabilis Naumov, Morbi Plantarum 14: 144. 1925.

Conidiomata aggregated in a black stroma at the ends of branchlets, globose, black, smooth, with central ostiole, up to 600 µm diam, papillate; wall of 3–8 layers of dark brown *textura*

Fig. 3. Conidia and conidiogenous cells of *Cytostagonospora photiniicola* (redrawn from Sutton 1980). Scale bar = 10 µm.

Fig. 4. Conidia and conidiogenous cells of *Dearnessia apocyni* (F43227). Scale bars = 10 µm.

Fig. 6. Conidia and conidiogenous cells of *Jahniella bohemica* (redrawn from Sutton 1980). Scale bar = 10 µm.

Fig. 7. *Jahniella bohemica* [K(M) 180917]. A. Vertical section through conidioma. B. Ostiolar region with loose cells. C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Fig. 8. Conidia and conidiogenous cells of *Megaloseptoria mirabilis* (MA-Fungi 6978-1). Scale bars = 10 µm.

Fig. 9. *Megaloseptoria mirabilis* (MA-Fungi 6978-1). A. Conidiomata on host tissue. B. Conidiogenous cells. C. Conidia. Scale bars = 10 µm.

angularis. Conidiogenous cells lining the cavity, subcylindrical to ampulliform, hyaline, smooth, 7–15 × 4–8 µm; proliferating percurrently near apex. Conidia solitary, sclecosporous, variously curved, subcylindrical, tapering in upper third to obtuse apex, base truncate, 3–4 µm diam, transversely 30–40-septate, (170–)200–250 × (5–)6(–7) µm.

Specimen examined: Switzerland, Zürich, St. Schnach., on branchlets of *Pinus pungens* var. *glauba* (Pinaceae), 10 July 1951, E. Müller, **holotype** MA-Fungi 6978-1.

Note: *Megaloseptoria* differs from *Septoria* in that the conidiomata are aggregated in a black stroma, which is not the case in *Septoria s. str.*

Phaeoseptoria Speg., Revista Mus. La Plata 15(2): 39. 1908.

Leaf spots angular-subcircular, 0.5–3 mm diam, becoming confluent. Conidiomata pycnidial, epiphyllous, subepidermal, black, 60–90 µm diam. Conidiogenesis cells hyaline, smooth, holoblastic (?). Conidia filiform, obclavate, smooth, 1–3-euseptate, medium brown, 30 × 3 µm (Saccardo & Trotter 1913, Walker *et al.* 1992, Crous *et al.* 1997).

Type species: *P. papayae* Speg., Revista Mus. La Plata 15(2): 39. 1908.

Notes: *Phaeoseptoria papayae* was originally described from leaf spots on *Carica papaya* collected in the São Paulo Botanical Garden, Brazil. Presently there are numerous clades that contain isolates conforming to this morphology, and this matter can only be resolved once fresh material of *P. papayae* has been recollected to clarify its phylogeny (see below).

Pseudoseptoria Speg., Ann. Mus. Nac. B. Aires, Ser. 3 13: 388. 1910.

Mycelium immersed, branched, septate, pale brown. Conidiomata pycnidial, solitary or linearly aggregated, immersed, brown, globose, unilocular; walls thin, of pale brown *textura angularis*. Ostiole distinct, central, circular. Conidiophores reduced to conidiogenous cells. Conidiogenous cells discrete, determinate or indeterminate, hyaline, smooth, ampulliform with a prominent cylindrical papilla with several percurrent proliferations at the apex. Conidia falcate, fusoid, acutely rounded at each end, hyaline, aseptate, guttulate, smooth, thin-walled (Sutton 1980).

Type species: *P. donacicola* Speg., Ann. Mus. Nac. B. Aires, Ser. 3 13: 388. 1910.

Note: Species of *Pseudoseptoria* are plant pathogenic to members of Poaceae.

Rhabdospora (Durieu & Mont. ex Sacc.) Sacc., Syll. Fung. (Abellini) 3: 578. 1884. nom. cons.

Basionym: *Septoria* sect. *Rhabdospora* Durieu & Mont., in Durieu, Expl. Sci. Alg. 1 (livr. 15): 592. 1849. [1846–1849].

Type species: *R. oleandri* Durieu & Mont., in Durieu, Expl. Sci. Alg. 1 (livr. 15): 593. 1849 [1846–1849].

Notes: *Rhabdospora* is a poorly defined genus, originally established to accommodate septoria-like species occurring on stems (Priest 2006). Of the 11 species treated by Sutton (1980), most are currently placed in *Septoria*. This genus is in need of revision pending the recollection of fresh material (on *Nerium oleander* from Algeria).

Sclerostagonospora Höhn., Hedwigia 59: 252. 1917.

Conidiomata pycnidial, immersed, separate, dark brown to black, globose, unilocular; walls thin, composed of thick-walled, dark brown *textura angularis*; ostiole single, circular, central, papillate. Conidiophores reduced to conidiogenous cells. Conidiogenous cells holoblastic, determinate, discrete, hyaline, smooth, ampulliform to irregular, formed from the inner cells of the pycnidial wall. Conidia subcylindrical, pale brown, thin-walled, minutely verruculose, 3-euseptate, sometimes slightly constricted at the septa (from Sutton 1980).

Type species: *S. heraclei* (Sacc.) Höhn., Hedwigia 59: 252. 1917.

Note: *Sclerostagonospora* differs from *Stagonospora* in having pigmented conidia.

Septoria (Sacc.) Sacc., Syll. Fung 3: 474. 1884. nom. cons.

Figs 10, 11.

= *Septaria* Fr., Novit. Fl. Svec. 5: 78. 1819. nom. rejic.

Mycelium slow-growing, pale brown, septate, immersed. Conidiomata pycnidial, immersed, separate or aggregated (but not confluent), globose, papillate (or not), brown, wall of thin, pale

Fig. 10. Conidia and conidiogenous cells of *Septoria cytisi* (BPI USO 378994). Scale bars = 10 µm.

brown *textura angularis*, inner layer of flattened, hyaline *textura angularis*, frequently somewhat darker and more thick-walled around the ostiole. Ostiole single, circular, central. Conidiophores reduced to conidiogenous cells. Conidiogenous cells holoblastic, either determinate or indeterminate, proliferating sympodially and/or percurrently, hyaline, smooth, ampulliform, dolliform or lageniform to short cylindrical; scars unthickened. Conidia hyaline, multiseptate, filiform, smooth, continuous or constricted at septa. Sexual states are mycosphaerella-like.

Type species: *S. cytisi* Desm., Ann. Sci. Nat. Bot. 8: 24. 1847.

Specimen examined: Slovakia, Muehlthal near Bratislava (Pressburg), on leaves of *Laburnum anagyroides* (Leguminosae), 1884, J.A. Baeumler, BPI USO 378994.

Note: The ITS and LSU sequences of this specimen were published respectively under GenBank accession numbers JF700932 and JF700954.

Stagonospora (Sacc.) Sacc., Syll. Fung. (Abellini) 3: 445. 1884. nom. cons.

Basionym: *Hendersonia* subgen. *Stagonospora* Sacc., Michelia 2 (no. 6): 8. 1880.

Conidiomata pycnidial, immersed, unilocular, globose, separate, ostiolate; walls of dark brown, thick-walled *textura angularis*, and on the inside of hyaline, thin-walled, flattened cells. Conidiophores reduced to conidiogenous cells. Conidiogenous cells doliform, hyaline, with several percurrent proliferations at the apex, formed from the inner cells of the pycnidial wall. Conidia hyaline, smooth to finely verruculose, 1–multiseptate, cylindrical or fusoid-ellipsoidal, straight or slightly curved, often guttulate, constricted or not at septa.

Type species: *S. paludosa* (Sacc. & Speg.) Sacc., Syll. Fung. (Abellini) 3: 453. 1884.

Stenocarpella Syd. & P. Syd., Ann. Mycol. 15(3–4): 258. 1917. Fig. 12.

Mycelium immersed, brown, branched, septate. Conidiomata pycnidial, separate or sometimes confluent, globose or elongated, dark brown, subepidermal, unilocular, thick-walled; walls composed of dark brown, thick-walled *textura angularis*. Ostiole single, circular, papillate, protruding. Conidiophores usually absent. Conidiogenous cells cylindrical, hyaline, determinate, discrete, phialidic, with collarette and minute periclinal thickening, lining the inner layer of the pycnidial wall. Conidia subcylindrical, straight or curved, fusiform, apex obtuse, base tapered, truncate, thick-walled, smooth-walled, granular, pale to medium brown, 0–3-euseptate. Beta conidia hyaline, scolocosporous, curved (Crous et al. 2006, Lampricht et al. 2011).

Type species: *S. zeae* Syd. & P. Syd., Ann. Mycol. 15(3–4): 258. 1917. [= *S. macrospora* (Earle) B. Sutton]

Specimens examined: South Africa, KwaZulu-Natal, Hlabisa, rain-damaged Bt Zea mays hybrid (Poaceae), 2003–04 season, J. Rheeder (**ex-epitype**, CBS 117560 = MRC 8615, designated in Crous et al. 2006); KwaZulu-Natal, Zea mays kernels, 2005, P. Caldwell, CPC 11863 = CBS 128560.

Notes: *Stenocarpella* presently contains two species, *S. macrospora* and *S. maydis*, both causing “*Diplodia* ear rot of maize”. These two taxa were previously assigned to *Diplodia* and *Macrodiploidia*, respectively (Petrak & Sydow 1927, Sutton 1964). Several years later, Sutton re-examining these taxa and placed them in their own genus, *Stenocarpella* (Sutton 1977, 1980). Recent phylogenetic studies confirmed that these taxa indeed cluster by themselves

Fig. 11. *Septoria cytisi* (BPI USO 378994). A. Leaf with symptoms. B. Close-up of leaf spot with conidiomata. C, D. Conidiogenous cells giving rise to conidia. E. Conidia. Scale bars = 10 µm.

Fig. 12. *Stenocarpella maydis* (top) and *S. macrospora* (bottom) (redrawn from Sutton 1980). Scale bars = 10 µm.

within the *Diaporthales* (Crous et al. 2006, Lamprecht et al. 2011), supporting the decision of Sutton (1980).

Trichoseptoria Cavara, Atti Ist. Bot. Univ. Lab. Crittig. Pavia 2: 40. 1892.

Type species: *T. alpei* Cavara, Atti Ist. Bot. Univ. Lab. Crittig. Pavia 2: 40. 1892.

Notes: Not much is known about this septoria-like genus, except that it is distinguished from *Septoria* by having setae on its pycnidia with 1–2-septate, hyaline conidia. This genus is in further need of revision once fresh material has been recollected (*Citrus vulgaris*, Belgiojoso, Alps).

Zymoseptoria Quaedvlieg & Crous, Persoonia 26: 64. 2011.

Conidiomata pycnidial, semi-immersed to erumpent, dark brown to black, subglobose, with central ostiole; wall of 3–4 layers of brown *textura angularis*. Conidiophores hyaline and smooth, 1–2-septate, or reduced to conidiogenous cells, lining the inner cavity. Conidiogenous cells are tightly aggregated and ampulliform to doliiform or subcylindrical, phialidic with periclinal thickening, or with 2–3 inconspicuous, percurrent proliferations at the apex. Conidia (Type I) solitary, hyaline, smooth, guttulate, narrowly cylindrical to subulate, tapering towards acutely rounded apex, with bluntly rounded to truncate base, transversely euseptate; hila not thickened nor darkened. On OA and PDA media plates the aerial hyphae disarticulate into phragmospores (Type II conidia) that again give rise to Type I conidia via microcyclic conidiation; yeast-like growth and microcyclic conidiation (Type III conidia) common on agar media (Quaedvlieg et al. 2011).

Type species: *Z. tritici* (Desm.) Quaedvlieg & Crous, Persoonia 26: 67. 2011.

Notes: *Zymoseptoria* was split off from *Septoria* s. str. and redescribed by Quaedvlieg et al. (2011) based on LSU sequence data when said authors delimitated *Septoria* s. str. by sequencing the ITS and LSU sequences out of *S. cytisi* herbarium material. Phylogenetic analysis showed that *Zymoseptoria* species cluster within a distinct clade inside the *Mycosphaerellaceae* that is closely related to *Ramularia*, but located distant from *Septoria* s. str.

Acervular forms

Asteromidium Speg., Ann. Soc. cient. argent. 26(1): 66. 1888. Figs 13, 14.

Mycelium immersed, branched, septate, hyaline. Conidiomata acervular, subcuticular, separate or confluent, pulvinate to doliiform, at the base, composed of hyaline to pale brown, thin-walled *textura angularis* which extends laterally, finally with separate cells dispersed in a mucilaginous matrix to form the overlying wall; cuticle discoloured and occasionally pseudoparenchymatous, walls adjacent to the upper epidermal wall also discoloured; dehiscence irregular. Conidiogenous cells holoblastic, discrete, indeterminate, ± cylindrical, hyaline, smooth, with 1–2 sympodial proliferations, scars unthickened, flat, formed from the basal and lateral walls. Conidia cylindrical to fusoid, gently tapered at each end, apex obtuse, base truncate, thin-walled, guttulate to granular, hyaline, 3-septate (Sutton 1980).

Type species: *A. imperspicuum* Speg., Ann. Soc. cient. argent. 26(1): 66. 1888.

Specimen examined: Paraguay, on leaves of Sapindaceae, 1883, isotype K(M) 180228, ex B. Balansa Pl. du Paraguay No. 4085.

Notes: This genus has to be recollected (Sapindaceae, Paraguay) to allow for a molecular comparison to other existing genera in this

Fig. 13. Conidia and conidiogenous cells of *Asteromidium imperspicuum* (redrawn from Sutton 1980). Scale bar = 10 µm.

Fig. 14. *Asteromidium imperspicuum* [K(M) 180228]. A. Conidiomata on host surface. B. Section through conidioma. C, D. Conidiogenous cells and conidia. Scale bars: B = 75 µm, all others = 10 µm.

complex. The morphology of the specimen examined correlates well with the description provided by Sutton (1980).

Ciferriella Petr., Ann. Mycol. 28(5/6): 409. 1930.

Type species: *C. domingensis* Petr. & Cif., Ann. Mycol. 28(5/6): 409. 1930.

= *Pseudocercospora* Speg., Anales Mus. Nac. Hist. Nat. B. Aires, Ser. 3, 20: 437. 1910.

Pseudocercospora domingensis (Petr. & Cif.) Quaedvlieg, Verkley & Crous, comb. nov. MycoBank MB804401. Figs 15, 16.

Basionym: *Ciferriella domingensis* Petr. & Cif., Ann. Mycol. 28(5/6): 409. 1930.

Leaf spots amphigenous, subcircular, medium brown with dark purple margin, 1.5–6 mm diam. Sporulation hypophyllous, fasciculate to sporodochial, brown, arising from a brown stroma, up to 50 µm diam. Conidiophores medium brown, smooth, subcylindrical, 0–2-septate, straight to once geniculate, 15–20 × 3–5 µm. Conidiogenous cells terminal, brown, smooth to finely verruculose, ampulliform to subcylindrical, proliferating sympodially or percurrently, tapering to a truncate apex, 2 µm diam, 10–15 × 3–4 µm. Conidia brown, smooth, straight to slightly curved, obclavate, apex subobtuse, base obconically truncate, 0–3-septate, 35–60 × 3–4 µm.

Specimen examined: Dominican Republic, on *Vitex umbrosa* (Lamiaceae), 26 May 1929, coll. R. Ciferri, det. F. Petrik, holotype ex N.Y. Bot. Gard. No 01048475.

Notes: The dimensions of the conidia and conidiophores correlate with the observations of Sutton (1980). However, the conidiomata are sporodochial to fasciculate, and not acervular. *Ciferriella domingensis* is a typical *Pseudocercospora* sensu Crous et al. (2013). Based on the species presently known from *Vitex* (Crous & Braun 2003), it appears to represent a distinct taxon, for which a new combination in *Pseudocercospora* is proposed.

Colletogloeum Petr., Sydowia 7: 368. 1953.

Mycelium immersed, branched, septate, hyaline to pale brown. Conidiomata acervular, epidermal to subepidermal, separate, occasionally confluent, composed of hyaline to pale brown, thin-walled *textura angularis*. Conidiophores hyaline to pale brown, sparsely branched, septate, smooth, cylindrical or slightly irregular, formed from

Fig. 15. Conidia and conidiogenous cells of *Pseudocercospora domingensis* (NY No 01048475). Scale bars = 10 µm.

the upper cells of the acervulus. Conidiogenous cells integrated or discrete, indeterminate, cylindrical or doliform, with several percurrent proliferations at apex. Conidia hyaline to pale brown, 0-multiseptate, straight, curved or irregular, truncate at the base, obtuse at the apex, usually thin-walled, smooth, guttulate or not.

Type species: *C. dalbergiae* (S. Ahmad) Petr., Sydowia 7: 369. 1953. [= *C. sissoo* (Syd.) B. Sutton, Mycol. Pap. 97: 14. 1964.]

Notes: The exact taxonomic position of *Colletogloeum* was unclear for a long time as it included many species that appear to represent asexual morphs of *Teratosphaeria*. Crous et al. (2009a–c) used ITS sequence data from a specimen representative of *C. sissoo* (IMI 119162) to demonstrate that the type of *Colletogloeum* clustered near the *Pseudocercospora* complex within the *Mycosphaerellaceae*.

Cylindrosporium Grev., Scott. crypt. fl. (Edinburgh) 1: pl. 27. 1822.

= *Cylindrodochium* Bonord., Handb. Allgem. mykol. (Stuttgart): 132. 1851.

Mycelium immersed, branched, septate, hyaline. Conidiomata acervular, white, slimy, subcuticular, separate or confluent, formed of pale brown to hyaline, thin-walled *textura angularis*; dehiscence irregular. Conidiophores hyaline, parallel, branched

Fig. 16. *Pseudocercospora domingensis* (NY No 01048475). A. Leaf spot. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

only at the base, 1–2-septate, smooth, formed from the upper pseudoparenchyma. *Conidiogenous cells* enteroblastic, phialidic, integrated, cylindrical, hyaline, smooth. *Conidia* straight or slightly curved, aseptate, cylindrical, thin-walled, smooth, hyaline, eguttulate (Sutton 1980).

Type species: *C. concentricum* Unger, Exanth. Pflanzen (Wien) 2: 9. 1833.

Notes: Sutton (1980), Von Arx (1983), Deighton (1987) and Braun (1990) could not agree on the taxonomic status of this genus, which is associated with light leaf spot of oil seed rape (sexual morph *Pyrenopeziza brassicae*). This genus is in need of revision, awaiting the recollection of fresh material of *C. concentricum* (on *Pulmonaria officinalis*, Germany).

Phloeospora Wallr., Fl. Crypt. Germ. (Norimbergae) 2: 176. 1833.

Mycelium immersed, septate, hyaline. *Conidiomata* acervular, subepidermal, circular, discrete or confluent, composed of hyaline to pale brown, thin-walled *textura angularis*; dehiscence irregular. *Conidiophores* reduced to conidiogenous cells or with one or two supporting cells, branched at base or not. *Conidiogenous cells* holoblastic, annellidic, occasionally also sympodial, discrete, indeterminate hyaline, smooth, cylindrical, with several apical inconspicuous annellations, formed from the upper cells of the acervuli. *Conidia* hyaline, septate, smooth, guttulate or not, cylindrical, curved, attenuated towards the apices, apex obtuse to subobtuse, base truncate, with minute marginal frill.

Type species: *P. ulmi* (Fr.) Wallr., Fl. Crypt. Germ. (Norimbergae) 2: 177. 1833.

Notes: Sexual morphs of *Phloeospora* have been linked to genera that resemble the concepts of *Mycosphaerella*, *Didymella* and *Sphaerulina*. Verkley & Priest (2000) already noted that this genus is heterogeneous and in need of revision. The phylogenetic analysis performed in this study confirmed that *Phloeospora* (based on *P. ulmi*) clusters close to, but separate from *Septoria* s. str. (Fig. 1).

Phloeospora Höhn., Ann. Mycol. 22: 201. 1924. Fig. 17.

Mycelium immersed, branched, septate, hyaline. *Conidiomata* acervular, subepidermal, ± circular, discrete, composed of hyaline

Fig. 17. Conidia and conidiogenous cells of *Phloeospora ceanothi* (redrawn from Sutton 1980). Scale bar = 10 µm.

to pale brown, thin-walled *textura angularis*. *Conidiogenous cells* holoblastic, sympodial, discrete, indeterminate, hyaline, smooth, lageniform to cylindrical, with 1–2 broad, flat unthickened apical scars, formed from the upper pseudoparenchyma. *Conidia* hyaline, 2-euseptate, thin-walled, smooth, guttulate, straight, curved or irregular, tapered gradually to an obtuse apex and abruptly to a truncate base (Sutton 1980).

Type species: *P. ceanothi* (Ellis & Everh.) Höhn., Ann. Mycol. 22(1–2): 201. 1924.

Notes: Not much is known of the sexual state of this genus, but *P. padi* has been linked to *Blumeriella jaapii* (Sutton 1980). A phylogenetic analysis performed on available isolates (unpubl. data) indicated that *Phloeospora* is polyphyletic. However, as the type is not known from culture (on *Ceanothus*, California, USA), this matter could not be resolved.

Septogloewum Sacc., Michelia 2(6): 11. 1880.

Mycelium immersed, branched, septate, hyaline. *Conidiomata* acervular, epidermal to subepidermal, separate or confluent, formed

of pale brown thin-walled pseudoparenchyma. *Conidiophores* short, stout, 1–2-septate, hyaline, smooth, branched at the base, formed from the upper pseudoparenchyma. *Conidiogenous cells* phialidic, discrete or integrated, determinate, cylindrical, doliiform to obpyriform, hyaline, smooth, with minute collarette and prominent periclinal thickening. *Conidia* hyaline, 1–3-euseptate, thin-walled, smooth, eguttulate, base truncate, apex obtuse, straight or curved, constricted, obovoid (Sutton 1980).

Type species: *S. carthusianum* (Sacc.) Sacc., *Michelia* 2(6): 11. 1880.

Notes: Although more than 120 species of *Septogloewum* have been described, the genus was reduced to just two species by Sutton & Pollack (1974). Sexual morphs have been linked to *Pleuroceras* in the *Diaporthales* (Monod 1983). The genus is in need of revision pending fresh collections.

Xenocylindrosporium Crous & Verkley, *Fungal Planet* 44. 2009.

Conidiomata immersed, black, opening by irregular rupture, acervuloid, up to 300 µm diam; wall consisting of 3–4 layers of pale brown *textura angularis*. *Conidiophores* hyaline, smooth, subcylindrical, branched, septate, or reduced to ampulliform conidiogenous cells. *Conidiogenous cells* hyaline, smooth, ampulliform to subcylindrical, terminal or lateral on septate conidiophores, monopodial with minute periclinal thickening. *Conidia* solitary, hyaline, smooth, curved, widest in middle, tapering to acutely rounded apex and truncate base, 0–1-septate.

Type species: *X. kirstenboschense* Crous & Verkley, *Fungal Planet* 44. 2009.

Stromatic forms

Dothistroma Hulbary, *Bull. III. Nat. Hist. Surv.* 21: 235. 1941.

Mycelium immersed, branched, septate, pale brown to hyaline. *Conidiomata* sometimes acervular, initially subepidermal later erumpent, composed of pale brown, thin-walled *textura angularis*, sometimes eustromatic, multilocular and of darker brown, thick-walled tissue. *Stromata* are strongly erumpent and finally pulvinate. *Conidiogenous cells* holoblastic, discrete, determinate, ampulliform, hyaline, smooth, non-proliferating, formed from the upper cells of stroma or from inner cells of the locular walls. *Conidia* hyaline, straight or curved, filiform, 1–5-euseptate, continuous, thin-walled and smooth (Barnes *et al.* 2004).

Type species: *D. pini* Hulbary, *Bull. III. Nat. Hist. Surv.* 21: 235. 1941.

Notes: *Dothistroma* sexual morphs are mycosphaerella-like (Evans 1984), and the two species of *Dothistroma* that have been subjected to DNA sequencing (*D. septosporum* and *D. pini*) cluster together in the “*Dothistroma* clade” as described by Crous *et al.* (2009a, c). Because of a lack of recognisable morphological characteristics, it is virtually impossible to discriminate between *D. septosporum* and *D. pini* without molecular tools (Barnes *et al.* 2004). Multiple morphological varieties of both *D. septosporum* and *D. pini* have

Fig. 18. Conidia and conidiogenous cells of *Phlyctaeniella humuli* (IMI 202260) (redrawn from Sutton 1980). Scale bar = 10 µm.

been described based on differences in conidia length alone (e.g. *D. septosporum* var. *keniense*). However, controversy exists as to whether spore size represents an adequate characteristic to distinguish among these *Dothistroma* varieties, as since the introduction of molecular tools only *D. septosporum* and *D. pini* have been confirmed as distinct species.

Phlyctaeniella Petr., *Ann. Mycol.* 20: 323. 1922. Fig. 18.

Mycelium immersed, branched, septate, hyaline. *Conidiomata* eustromatic, separate, immersed, pale brown, globose, unilocular, scarcely erumpent; side wall and base of several cell layers of hyaline, thin-walled *textura angularis*, above of larger pale brown tissue. *Ostiole* indistinct, and dehiscence by rupture of the upper wall. *Conidiophores* hyaline, smooth, septate, irregularly branched, especially at the base, formed from the inner cells of the stroma wall. *Conidiogenous cells* phialidic, integrated or discrete, determinate, hyaline, markedly tapered at the apices, smooth, with apical or lateral apertures, collarette minute, with periclinal thickening; only rarely becoming percurrent. *Conidia* hyaline, smooth, thin-walled, irregularly guttulate, filiform, straight, curved or irregular, multisepitate (Sutton 1980).

Type species: *P. polonica* Petr., *Ann. Mycol.* 20: 323. 1922.

Note: Fresh material needs to be collected of this taxon (on *Aruncus silvestris*, Austria), before its taxonomy can be resolved.

Septocyta Petr., *Ann. Mycol.* 25: 330. 1927. Figs 19, 20.

Mycelium immersed, branched, septate, hyaline to pale brown. *Conidiomata* eustromatic, immersed, separate, erumpent, dark brown to black, finally opening widely, unilocular, multilocular or convoluted, thick-walled; wall of pale brown, thin-walled *textura angularis* except in the dehiscent region which is darker brown and more thick-walled. *Ostiole* absent, dehiscence by breakdown of the upper wall. *Conidiogenous cells* are holoblastic, sympodial with 1–3

Fig. 19. Conidia and conidiogenous cells of *Septocya ramealis* (PDD 51271). Scale bars = 10 µm.

apical, scarcely protruding, unthickened denticles, indeterminate, discrete, ampulliform to lageniform, hyaline, smooth, formed from the inner cells of the locular walls. *Conidia* hyaline, 1–3 euseptate, smooth, straight or slightly curved, acicular, apex obtuse, base truncate, often with minute guttules associated with septa (Sutton 1980).

Type species: *S. ramealis* (Roberge ex Desm.) Petr., Ann. Mycol. 25: 330. 1927.

Septocya ramealis (Roberge ex Desm.) Petr., Ann. Mycol. 25: 330. 1927.

Conidiomata eustromatic to pycnidial, black, up to 160 µm diam, aggregated in clusters, erumpent through ruptures in epidermis, convoluted; wall of 3–8 layers of brown *textura angularis*. *Conidiophores* lining the inner cavity, reduced to conidiogenous cells, or one or two supporting cells. *Conidiogenous cells* hyaline, smooth, ampulliform, proliferating sympodially and percurrently near apex, also with lateral denticle-like protrusions, 6–12 × 2.5–4 µm. *Conidia* hyaline, smooth, guttulate, (9–)20–30(–35) × 1.5(–2) µm, 1(–3)-septate, irregularly curved, subcylindrical, apex obtuse, base tapering slightly to truncate hilum, 0.5 µm diam.

Specimen examined: Germany, Brandenberg, on *Rubus fruticosus* (Rosaceae), 7 June 1923, coll. P. Sydow, det. H. Sydow, Sydow Mycoh. Germ. PDD 51271.

Notes: *Septocya ramealis*, the type of *Septocya*, has a long list of synonyms. The specimen examined here (PDD 51271), differs somewhat from the description provided by Sutton (1980), and appears to represent a species of *Septoria* s. str., as the mode of conidiogenesis is not that different. Presently there is a single ITS sequence labelled as *S. ruborum* available on GenBank (JN133277.1), placing it in the middle of *Septoria* s. str. As no type material of *S. ramealis* could be located, this matter remains unresolved.

Septopatella Petr., Ann. Mycol. 23: 128. 1925.

Mycelium immersed, branched, septate, hyaline to subhyaline. *Conidiomata* superficial, often subtended by a superficial, pale brown, septate, branched mycelium, pulvinate, separate to occasionally aggregated, dark brown to black, finally opening widely, cupulate; basal wall of small-celled, brown, thin-walled *textura angularis*, becoming *textura porrecta* as it merges into the periclinal walls; a hypostroma attaches the conidioma to the substrate; *Ostiole* absent. *Conidiophores* hyaline, septate, branched at the base, thin-walled, cylindrical, formed from the gelatinized basal wall of the conidioma. *Conidiogenous cells* holoblastic, sympodial, integrated, indeterminate, cylindrical, hyaline, smooth, produced as 2–3 branches from the apex of the conidiophores. *Conidia* hyaline, 3–4-euseptate, thin-walled, smooth, minutely guttulate, straight or curved, occasionally irregularly filiform (Dyko & Sutton 1979, Sutton 1980).

Type species: *S. septata* (Jaap) Petr., Ann. Mycol. 23: 129. 1925.

Note: Not much is known about this genus, and as no cultures of *S. septata* are presently available (on *Pinus montana*, Czech Republic) this matter cannot be resolved.

Stictosepta Petr., Sydowia 17: 230. 1964. [1963]. Fig. 21.

Mycelium immersed, branched, septate, hyaline. *Conidiomata* eustromatic, immersed, globose to collabent, papillate, unilocular, often convoluted, hyaline; walls thick, of hyaline, thin-walled

Fig. 20. *Septocya ramealis* (PDD 51271). A. Conidiomata on host tissue. B, C. Conidiogenous cells. D. Conidia. Scale bar = 10 µm.

Fig. 21. Conidia and conidiogenous cells of *Stictosepta cupularis* (redrawn from Sutton 1980). Scale bar = 10 µm.

textura intricata. Ostiole central and circular, single, furfuraceous. Conidiophores hyaline, septate, branched, anastomosing, formed from the inner cells of the locular wall. Conidiogenous cells sympodial or synchronous, integrated, indeterminate, hyaline, thin-walled, with usually two small, unthickened, apical, slightly protuberant conidiogenous loci. Conidia hyaline, thin-walled, smooth, multiseptate, slightly constricted at the septa, each cell medianly guttulate, straight or curved, base truncate, apex obtuse (Sutton 1980).

Type species: *S. cupularis* Petr., Sydowia 17: 230. 1964. [1963].

Note: Not much is known about this genus, but as no isolate of *S. cupularis* is presently available (on stems of *Fraxinus*, Czech Republic), it will not be treated here.

Sexual morphs linked to *Septoria*

Several sexual genera have been linked to *Septoria* and allied genera in literature, but very few have been confirmed in culture. Most sexual states cluster in the *Mycosphaerella* complex.

Mycosphaerella Johanson, Öfvers. K. Svensk. Vetensk.-Akad. Förhandl. 41(no. 9): 163. 1884.

= *Ramularia* Unger, Exanth. Pflanzen (Wien): 119. 1833.

Mycelium immersed to superficial, septate, hyaline, branched. *Caespituli* usually whitish to greyish on host tissue. Conidiophores fasciculate to synnematal, rarely solitary, or forming small sporodochia, emerging through stomata, from inner hyphae or stromata; conidiophores straight, subcylindric to geniculate-sinuous, aseptate or septate, hyaline, occasionally branched, smooth, rarely rough. Conidiogenous cells integrated, terminal, polyblastic, elongating sympodially, apex more or less straight to geniculate-sinuous or strongly curved, cicatrized, conidial scars hardly to conspicuously thickened, but always darkened, refractive. Conidia solitary to catenate, sometimes in branched chains, 0–4(–multi)-septate, hyaline, ellipsoid-ovoid to cylindrical-fusoid, rarely filiform, occasionally constricted at the septa, smooth

to verruculose-echinulate; hila distinct, slightly to conspicuously thickened, darkened, refractive; conidial secession schizolytic. Ascomata immersed to superficial, uniloculate, globose to subglobose with papillate, central, periphysate ostiole, dark brown to black, scattered or gregarious. Peridium of 3–6 layers of thin- to thick-walled *textura angularis*, dark brown to black. Hamathecium dissolves at maturity, and no stromatic tissue remains between the ascii. Ascii bitunicate, fissitunicate, 8-spored, cylindrical to cylindroclavate, ovoid to ampulliform or saccate, sessile to subsessile, apex rounded with distinct or indistinct ocular chamber. Ascospores bi- to tri- or multiseriate, ellipsoid-fusoid to obclavate or subcylindrical, hyaline, medianly 1-septate, often constricted at the septum, smooth-walled, granular to guttulate, mostly lacking any sheath.

Type species: *Ramularia pusilla* Unger, Exanth. Pflanzen (Wien): 169. 1833.

Notes: Species of *Ramularia* (including the *Mycosphaerella* sexual morph) have evolved over a broad developmental and physiological adaptation range that includes endophytes, saprophytes and symbionts. However, for a major part *Ramularia* consists of a wide range of narrow host range, foliicolous plant pathogens which are the cause of significant economical losses in both temperate and tropical crops worldwide (Crous et al. 2001). Verkley et al. (2004) showed that *Mycosphaerella* s. str. (linked to *M. punctiformis*) was in fact restricted to species with *Ramularia* anamorphs, leaving many “*Mycosphaerella*” species to be disposed to other genera. In employing the one fungus = one name concept (Hawksworth et al. 2011, Wingfield et al. 2012), the choice is to use *Ramularia* over *Mycosphaerella*, as the former is monophyletic and recently monographed (Braun 1995, 1998), while *Mycosphaerella* is poly- and paraphyletic, and consists of more than 40 genera, many as yet untreated (Crous et al. 2009c)

Sphaerulina Sacc., Michelia 1(no. 4): 399. 1878.

Ascomata pseudothecial, immersed, subepidermal, erumpent at the top, single to clustered, globose, papillate. Ostiole central, with hyaline periphyses; wall of *textura angularis*, composed of 2–4 layers of brown cells. Hamathecium dissolving at maturity. Ascii bitunicate, fissitunicate, clustered, cylindrical to obclavate, rounded at apex, with or without a shallow apical chamber, short-stipitate or sessile, with 8 bisetate to triseriate ascospores. Ascospores subcylindrical to fusiform, rounded at ends, slightly tapered, straight or slightly curved, 1–3-septate, with a primary septum nearly median, hyaline, smooth, without sheath or appendages.

Type species: *Sphaerulina myriadea* (DC.) Sacc., Michelia 1(no. 4): 399. 1878.

Notes: The genus *Sphaerulina* was chiefly separated from *Mycosphaerella* on the basis of ascospore septation (Crous et al. 2011). *Sphaerulina myriadea*, which occurs on hosts in the Fagaceae, appears to be a species complex. Results in this paper show that *Sphaerulina myriadea* clusters together with many septoria-like species in a clade that is distinct, but very closely related to *Septoria* s. str. The septoria-like species in this *Sphaerulina* clade were subsequently rediscribed in *Sphaerulina*. Species including ones with 1-septate ascospores and septoria-like asexual morphs are treated below and by Verkley et al. (2013).

Treatment of phylogenetic clades

Based on the phylogenetic data generated in this study, we were able to delineate several clades in the *Septoria* complex. Recognised clades, as well as novel species and genera, are described and discussed below. Taxa with descriptions that are freely available online in MycoBank or open access journals, are not repeated here.

Clade 1: *Septoria*

Description: See above.

Type species: *S. cytisi* Desm., Ann. Sci. Nat. Bot. 8: 24. 1847.

Septoria cf. agrimoniicola Bondartsev, Mater. mikol. obsléed. Ross. 2: 6. 1921.

Leaf spots on the upper leaf surface, distinct, scattered, brown with purplish margin, circular to angular, sometimes vein-limited, discrete lesions 2–4 mm diam, reaching 10 mm wide when confluent, finally the center becoming pale colored to nearly whitish; on the lower leaf surface similar but discoloured (Shin & Sameva 2004). On sterile Carex leaves on WA. *Conidiomata* pycnidial, separate but frequently aggregated and linked by brown stromatic tissue in a stroma; globose, black, exuding a creamy conidial mass via a central ostiole; conidiomata up to 350 µm diam; wall of 6–12 layers of dark brown, thick-walled *textura angularis*. *Conidiophores* reduced to conidiogenous cells or 1–2 supporting cells, hyaline, subcylindrical, lining the inner layer of conidioma. *Conidiogenous cells* hyaline, smooth, subcylindrical to ampulliform, 10–17 × 3–4 µm; proliferating sympodially but also percurrently near apex. *Conidia* hyaline, smooth, guttulate, filiform, apex subobtuse, base long obconically truncate, 1–4-septate, (20–)25–35(–40) × 1.5–2(–2.5) µm; microcyclic conidiation observed.

Culture characteristics: Colonies on PDA flat, undulate with sparse, white aerial mycelium, surface olivaceous-black, reverse olivaceous-black, after 14 d, 3.5 cm diam; on MEA with sparse white aerial mycelium, surface olivaceous-black, reverse olivaceous-black, after 14 d, 5 cm diam; on OA with sparse white aerial mycelium, surface olivaceous, reverse olivaceous, after 14 d, 3 cm diam.

Specimen examined: South Korea, Guri, on leaves of *Agrimonia pilosa* (Rosaceae), 11 Jul. 2009, H.D. Shin (CBS H-21279, culture CBS 128602 = KACC 44644 = SMKC 24292).

Notes: This fungus was first reported from Korea by Shin & Sameva (2002) as *S. agrimoniicola*, and fits well with the original description of this European taxon. However, fresh European collections and cultures are required for comparison, as *S. agrimoniicola* may well be restricted to Europe.

Septoria cf. stachydicola Hollós, Mathem. Természettud. Közlem. Magg. Tudom. Akad. 35(1): 60. 1926.

Leaf spots on the upper leaf surface distinct, scattered, brown with purplish margin, circular to angular, sometimes vein-limited, discrete lesions 2–4 mm diam, reaching 10 mm wide when

confluent, finally the center becoming paler or nearly whitish; on the lower leaf surface similar but discoloured (Shin & Sameva 2004). On OA. *Conidiomata* solitary to aggregated, black, globose, becoming somewhat papillate, up to 250 µm diam, opening by means of central ostiole, up to 40 µm diam; wall of 6–8 layers of thick-walled, brown *textura angularis*; exuding a creamy conidial mass. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner wall layer, hyaline, discrete, ampulliform to lageniform, 4–10 × 3–5 µm, proliferating sympodially or percurrently with inconspicuous proliferations. *Conidia* filiform, curved or flexuous, rarely straight, (60–)65–75(–90) × 1.5–2(–3) µm, hyaline, guttulate, 4–7(–11)-septate, apex subobtuse, slightly tapering from basal septum to truncate base, 1.5–2 µm.

Culture characteristics: Colonies on PDA erumpent, with feathery margin, with sparse white aerial mycelium, surface greenish-black, reverse olivaceous-black, after 14 d, 2.5 cm diam; on MEA with sparse white aerial mycelium, surface cinnamon to olivaceous-black in the younger patches, reverse cinnamon to olivaceous-black in patches, after 14 d, 4 cm diam; on OA with sparse white aerial mycelium, surface greenish-black, reverse fuscous-black, after 14 d, 3 cm diam.

Specimen examined: South Korea, Incheon, leaf of *Stachys riederi* var. *japonica* (Lamiaceae), 14 Aug. 2008, H.D. Shin (CBS H-21278, culture CBS 128668 = KACC 44796 = SMKC 24663).

Note: The Korean collection was originally identified as *Septoria stachydicola*, which fits the original description provided for this taxon (Shin & Sameva 2004). However, authentic European material is required for a comparison to confirm this identification, as we suspect *S. stachydicola* may be restricted to Europe.

Septoria cretae Quaedvlieg, Verkley & Crous, sp. nov.
MycoBank MB804402. Figs 22, 23.

Etymology: Named after Crete, the island from where it was collected.

On sterile Carex leaves on WA. *Conidiomata* up to 250 µm diam, brown, immersed, subepidermal, pycnidial, subglobose with central

Fig. 22. Conidia and conidiogenous cells of *Septoria cretae* (CBS 135095). Scale bar = 10 µm.

Fig. 23. *Septoria cretae* (CBS 135095). A. Colony sporulating in culture. B–F. Conidiophores and conidiogenous cells giving rise to conidia. G. Conidia. Scale bars = 10 µm.

ostiole, exuding creamy conidial mass; wall of 2–3 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells, or with a supporting cell that gives rise to several conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to subcylindrical, straight to curved, proliferating sympodially near apex, 10–20 × 2–3.5 µm. Conidia hyaline, smooth, thin-walled, subcylindrical to narrowly obclavate, granular, with subobtuse apex and obconically truncate to truncate base, 1–3-septate, (8–)15–22(–27) × 2(–3) µm.

Culture characteristics: Colonies on PDA erumpent, with feathery margin, lacking aerial mycelium, surface fuscous-black, reverse olivaceous-black, after 14 d, 3.5 cm diam; on MEA surface fuscous-black, reverse olivaceous-black, after 14 d, 4 cm diam; on OA surface fuscous-black, reverse fuscous-black, after 14 d, 3.5 cm diam.

Specimen examined: Greece, Crete, on leaves of *Nerium oleander* (Apocynaceae), 7 Jul. 2012, U. Damm, (holotype CBS H-21277, culture ex-type CBS 135095).

Notes: Several species of *Septoria* are known on *Nerium oleander*, namely *S. juliae* [conidia 1–6(–7)-septate, 26–54 × 2.5–5.5 µm], *S.*

neriicola (conidia 1-septate, 30–40 × 0.7–1 µm), *S. oleandriicola* [conidia 1–3-septate, 12.5–22.5–37.5(–40) × 2.5–3(–4.5) µm], *S. oleandrina* (conidia 0–1-septate, 9–19 × 1–1.5 µm), and *S. roll-hansenii* (conidia 0–4-septate, 25–39 × 3–4 µm) (Bedlan 2011), which differ from *S. cretae* based on conidial dimensions and septation.

Septoria glycincicola Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804403. Fig. 24.

Etymology: Named after the host genus on which it was collected, *Glycine*.

On OA. Conidiomata forming in concentric circles, pycnidial, separate, black, globose, up to 150 µm diam, opening by a central ostiole, up to 30 µm diam, exuding a creamy conidial mass; wall consisting of 3–6 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells lining the inner cavity, hyaline, smooth, ampulliform, 10–16 × 2.5–3.5 µm, proliferating sympodially near apex, holoblastic.

Fig. 24. *Septoria glycincicola* (CBS 128618). A, B. Colonies sporulating on PDA. C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Conidia hyaline, smooth, guttulate to granular, subcylindrical to narrowly obclavate, irregularly to gently curved, apex subobtuse, base long obconically truncate, 3–6-septate, (33–)45–55(–65) × (1.5–)2 µm.

Culture characteristics: Colonies on PDA flat, circular, with sparse black aerial mycelium with black tufts, surface patches of olivaceous-black to fawn in the younger parts, reverse with patches of olivaceous-black in the older parts to mouse-grey and pale purplish grey in the younger mycelium, after 14 d, 6.5 cm diam, pinkish exudate; on OA lobate, with sparse white aerial mycelium, surface patches of vinaceous to olivaceous-black, reverse fuscous-black to vinaceous-buff, after 14 d, 8.5 cm diam, pinkish exudate; on MEA with radial lobes, very short white aerial mycelium, surface fuscous-black, reverse olivaceous-black; after 14 d, 4.5 cm diam.

Specimen examined: South Korea, Namyangju, on leaves of *Glycine max* (Fabaceae), 22 Sep. 2008, H.D. Shin (**holotype** CBS H-21270, culture ex-type CBS 128618 = KACC 43091 = SMKC 22879).

Notes: *Septoria glycines* is the common *Septoria* species associated with brown spot of soybeans. *Septoria glycincola* is distinct from *S. glycines* (conidia 1–4 septate, 21–45 × 1.5–2 µm) in that it has larger conidia.

Septoria oenanthicola Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804405. Fig. 25.

Etymology: Named after the host genus from which it was collected, *Oenanthe*.

On sterile *Carex* leaves on WA. *Conidiomata* pycnidial, separate but aggregated, black, globose, up to 200 µm diam, opening by central ostiole, up to 20 µm diam, exuding a creamy conidial mass; wall consisting of dark brown, thickened, 6–10 layers of *textura angularis*. *Conidiophores* reduced to conidiogenous cells or to one

supporting cell. *Conidiogenous cells* hyaline, smooth, 3–5 × 3–7 µm, ampulliform, proliferating sympodially near apex, holoblastic. *Conidia* hyaline, smooth, guttulate, subcylindrical to narrowly obclavate, apex subobtuse, base long obconically truncate, 1–6-septate, (17–)25–45(–55) × (2–)2.5(–3) µm.

Culture characteristics: Colonies on PDA flat, undulate with sparse, white aerial mycelium, surface olivaceous-grey, reverse olivaceous, after 14 d, 2.5 cm diam; on MEA with sparse, white aerial mycelium, surface olivaceous-grey, reverse olivaceous-black, after 14 d, 5 cm diam; on OA with sparse white aerial mycelium, surface olivaceous-grey, reverse olivaceous, after 14 d, 3 cm diam.

Specimen examined: South Korea, Yangpyeong, on leaves of *Oenanthe javanica* (Apiaceae), 25 May 2006, H.D. Shin (**holotype** CBS H-21281, culture ex-type CBS 128649 = KACC 42394 = SMKC 21807).

Notes: This fungus was originally recorded from Korea by Shin (1998) as *Septoria oenanthidis*. However, conidia of Korean specimens (30–60 × 1.5–2.5 µm; Shin & Sameva 2004) are much larger than that of the American type collection (20–35 × 1.5–2 µm; Saccardo 1895), and therefore better treated as a separate taxon.

Septoria pseudonapelli Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804404. Fig. 26.

Etymology: Named after its morphological similarity to *Septoria napelli*.

Leaf spots on the upper leaf surface, scattered to confluent, distinct, angular to irregular, usually vein-limited, small to large, up to 30 mm when confluent, at first appearing small angular brown discolouration, later turning blackish brown with or without distinct border line, finally central area becoming blackish and surrounded by pale greenish margin; on the lower leaf surface similar but discoloured (Shin

Fig. 25. *Septoria oenanthicola* (CBS 128649). A. Colony sporulating on MEA. B. Section through conidiomata. C–G. Conidiogenous cells. H. Conidia. Scale bars: B = 200 µm, all others = 10 µm.

Fig. 26. *Septoria pseudonapelli* (CBS 128664). A. Colony sporulating on PDA. B. Section through conidioma. C–E. Conidiogenous cells. F. Conidia. Scale bars: B = 125 µm, all others = 10 µm.

& Sameva 2004). On sterile *Carex* leaves on WA. *Conidiomata* pycnidial, separate, black, globose, papillate with short neck (at times 1–2 necks develop), up to 250 µm wide, 500 µm high with central ostiole; wall of 5–7 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* ampulliform, lining the inner cavity, hyaline, smooth, with sympodial or apical percurrent proliferation, 10–13 × 5–7 µm. *Conidia* filiform, curved to flexuous, (50–)75–90(–100) × (2.5–)3(–3.5) µm, hyaline, guttulate, 4–10-septate, apex subobtuse, base obconically truncate, 2 µm diam.

Culture characteristics: Colonies on PDA flat, undulate with sparse, white aerial mycelium, surface olivaceous-black, reverse olivaceous-black, after 14 d, 2 cm diam; on MEA with sparse white aerial mycelium, surface olivaceous-black, reverse olivaceous-black, after 14 d, 4 cm diam; on OA with sparse white aerial mycelium, surface olivaceous, reverse olivaceous, after 14 d, 2 cm diam.

Specimen examined: South Korea, Chuncheon, on leaves of *Aconitum pseudolaeve* var. *erectum* (*Ranunculaceae*), 4 Sep. 2008, H.D. Shin (holotype CBS H-21280, culture ex-type CBS 128664 = KACC 43952 = SMKC 23638).

Notes: This taxon was originally reported as *Septoria napelli* from Korea by Shin & Sameva (2004), and broadly corresponds with the original description provided for this taxon (Petrak 1957). However, we have examined European material authentic for the name (see Verkley *et al.* 2013, this issue), from which the Korean fungus is genetically different. Based on these observations we describe the Korean collection as new.

Clade 2: *Sphaerulina*

Sphaerulina Sacc., *Michelia* 1(no. 4): 399. 1878.

Description: See above.

Type species: *Sphaerulina myriadea* (DC.) Sacc., *Michelia* 1(no. 4): 399. 1878.

Specimens examined: Germany, Driesen, Lasch [Rabenhorst, *Fungi Eur.* no. 149] (L). Japan, Aomori, Tsugaru, Kidukuri, Bense-marsh (40°51'53" N, 140°17'42"E), on leaves of *Q. dentata*, 21 Apr. 2007, K. Tanaka 2243 (HHUF 29940; single ascospore culture CBS 124646 = JCM 15565). UK, on leaves of *Quercus robur*

(*Fagaceae*), J.E. Vize [Microfungi Brit. Ex. No. 195] (ex IMI 57186, K(M) 167735). USA, California: Sequoia National Park, alt. 2590 m, on leaves of *Castanopsis sempervirens*, 18 Jun. 1931, H.E. Parks (BPI 623686); Lake Co., Hoberg's Resort, on leaves of *Q. kelloggii*, 15 May 1943, V. Miller (BPI 623707); Maryland, Marlboro, on leaves of *Q. alba*, 26 Apr. 1929, C.L. Shear (BPI 623705); Texas, Houston, on leaves of *Q. alba*, 8 Apr. 1869, H.W. Ravenel (BPI 623704).

Notes: Sivanesan (1984) linked *Sphaerulina* to *Septoria*, *Cercospora* and *Cercosporella* asexual morphs, though these were never confirmed based on DNA data. The latter two genera have since been shown to be distinct (Crous *et al.* 2013, Groenewald *et al.* 2013; this volume), which leaves septoria-like asexual morphs such as *Sphaerulina rubi* Demaree & Wilcox (linked to *Cylindrosporium rubi* Ellis & Morgan), and *S. rehmiana* (linked to *Septoria rosae*), which confirms the results obtained here (Fig. 1).

***Sphaerulina abeliceae* (Hiray.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804406.

Basionym: *Septoria abeliceae* Hiray., Mem. Col. Agr. Kyoto. Imp. Univ. 13(3): 33. 1931.

Specimen examined: South Korea, Jeonju, on leaves of *Zelkova serrata* (*Ulmaceae*), 29 Oct. 2006, H.D. Shin, CBS 128591 = KACC 42626.

***Sphaerulina amelanchier* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804407. Figs 27, 28.

Etymology: Named after the host genus from which it was collected, *Amelanchier*.

On sterile *Carex* leaves on WA. *Conidiomata* pycnidial, brown, separate, immersed, globose, up to 150 µm diam, exuding a creamy conidial mass via central ostiole; wall of 3–6 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* hyaline, smooth, subcylindrical, irregularly curved, branched to once geniculate-sinuous, 5–20 × 3–4 µm; proliferating sympodially. *Conidia* hyaline, smooth, guttulate, filiform, narrowly obclavate, apex subacutely rounded, base long obconically truncate, 1–8-septate, (25–)40–55(–60) × (1.5–)2(–2.5) µm; microcyclic conidiation common. *Ascomata* globose, brown,

Fig. 27. Conidia, conidiogenous cells, ascospore and ascus of *Sphaerulina amelanchier* (CBS 135110). Scale bars = 10 µm.

Fig. 28. *Sphaerulina amelanchier* (CBS 135110). A. Colony on PDA. B. Conidiogenous cells. C. Ascomata on host tissue. D. Germinating ascospore. E, F. Ascii. G. Ascospores. H. Conidia. Scale bars = 10 µm.

separate, immersed to erumpent, up to 150 µm diam. Ascii broadly ellipsoid to obclavate, 22–35 × 7–9 µm; apical chamber visible, 1–1.5 µm diam. Ascospores fusoid-ellipsoid, hyaline, smooth, granular, not to slightly constricted at median septum, widest just above septum, prominently curved, (13–)17–20(–25) × (2.5–)3(–3.5) µm. Ascospores germinating from both ends, with germ tubes parallel to the long axis, developing lateral branches and becoming constricted at septum, 3–4 µm diam.

Culture characteristics: Colonies on PDA radially striate with lobate edge, sparse white aerial mycelium, surface fuscous-black to buff for the younger tissue, reverse cinnamon to olivaceous-black, after

14 d, 3 cm diam; on MEA surface patches of hazel to fawn to fuscous-black, reverse sepia to olivaceous-black, after 14 d, 4.5 cm diam; on OA surface pale-vinaceous to fuscous-black, reverse cinnamon to fuscous-black, after 14 d, 3 cm diam.

Specimen examined: Netherlands, Houten, on leaf litter of *Amelanchier* sp. (Rosaceae), 28 Mar. 2012, S. Videira (holotype CBS H-21282, culture ex-type CBS 135110 = MP8 = S544).

Note: Presently there are no known species of septoria-like fungi known from *Amelanchier*. Phylogenetically, it is similar to *Sphaerulina rhabdoclinis* (conidia 8–30 × 1.5–2 µm), which infects needles of *Pseudotsuga menziesii*. Phylogenetically similar

isolates occur on *Betula*, *Castanea* and *Quercus*. More isolates and molecular data are required to resolve this complex.

***Sphaerulina azaleae* (Voglino) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804408.

Basionym: *Septoria azaleae* Voglino, Syll. Fung. (Abellini) 14(2): 976. 1899.

≡ *Phloeospora azaleae* (Voglino) Priest, Fungi of Australia: 224. 2006.

Specimens examined: Belgium, on leaves of *Rhododendron* sp. (Ericaceae), J. van Holder, CBS 352.49. South Korea, Hongcheon, on leaves of *Rhododendron* sp., 18 Oct. 2009, H.D. Shin, KACC 44865 = CBS 128605.

***Sphaerulina berberidis* (Niessl) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804409.

Basionym: *Septoria berberidis* Niessl, in Rabenhorst, Bot. Ztg. 24: 411. 1866.

= *Sphaerella berberidis* Auersw., in Gonnermann & Rabenhorst, Mycol. eur. Abbild. Sämmtl. Pilze Eur. 5-6: 3. 1869 (nom. nov. for *Sphaeria berberis* Nitschke ex Fuckel).

≡ *Mycosphaerella berberidis* (Auersw.) Lindau, in Engler & Prantl, Nat. Pflanzenfam., Teil. I (Leipzig) 1(1): 424. 1897.

Description in vitro (CBS 116724): Colonies on OA 16–20 mm diam after 14 d, with an even, colourless margin; colonies spreading to restricted, somewhat elevated in the centre, the surface covered by a dense mat of pure white, woolly aerial mycelium; reverse in the centre dark brick to brown vinaceous, surrounded by cinnamon tinges; small amounts of a yellow to greenish pigment diffuses into the surrounding medium. Colonies on MEA 8–10 mm diam after 14 d, with an even to slightly ruffled vinaceous buff margin; colonies restricted, pustulate, the surface ochraceous or darker, with diffuse to locally more dense finely felted grey aerial mycelium; reverse brown vinaceous to vinaceous buff. Culture remained sterile.

Specimen examined: Switzerland, Kt. Graubünden, Rodels-Realta, on *Berberis vulgaris* (Berberidaceae), 2 Jun. 1951, E. Müller, specimen CBS-H4984, culture CBS 324.52.

***Sphaerulina betulae* (Pass.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804410.

Basionym: *Septoria betulae* Pass., Primo Elenc. Funghi Parm.: no. 52. 1867.

Specimens examined: Netherlands, Olst, leaves of *Betula pubescens* (Betulaceae), Sep. 2004, S. Green, CBS 116724. South Korea, Hongcheon, leaves of *B. platyphylla* var. *japonica*, 27 May 2008, H.D. Shin, CBS 128600 = KACC 43769.

***Sphaerulina cercidis* (Fr.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804411.

Basionym: *Septoria cercidis* Fr., in Léveillé, Ann. Sci. Nat., Bot., Sér. 3 9: 251. 1848.

= *Septoria provincialis* Crous, Stud. Mycol. 55: 127. 2006.

Specimens examined: Argentina, La Plata, on *Cercis siliquastrum* (Caesalpiniaceae), 12 Feb. 2008, H.D. Shin, KACC 43596 = CBS 129151; on *C. siliquastrum*, 1 Sep. 2007, H.D. Shin, KACC 44497 = CBS 128634. France, Provence, Cheval Blanc camping site, on leaves of *Eucalyptus* sp., 29 Jul. 2005, P.W. Crous, holotype of *S. provincialis*, CBS H-19701, culture ex-type CBS 118910. Netherlands, on *C. siliquastrum*, Sep. 1950, G. van den Ende, CBS 501.50.

***Sphaerulina menispermi* (Thüm.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804412.

Basionym: *Septoria menispermi* Thüm., Pilzflora Siber.: no. 818. 1880.

Specimens examined: South Korea, Chuncheon, on leaves of *Menispernum dauricum* (Menispermaceae), 16 Jun. 2008, H.D. Shin, KACC 43848 = CBS 128761; Pyeongchang, on leaves of *M. dauricum*, 23 Sep. 2008, H.D. Shin, KACC 43968 = CBS 128666.

***Sphaerulina musiva* (Peck) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804413.

Basionym: *Septoria musiva* Peck, Ann. Rep. N.Y. St. Mus. Nat. Hist. 35: 138. 1883 [1881]

= *Mycosphaerella populorum* G.E. Thomps., Phytopathology 31: 246. 1941.

≡ *Davidiella populorum* (G.E. Thomps.) Aptroot, CBS Diversity Ser. (Utrecht) 5: 164. 2006.

= *Cylindrosporium oculatum* Ellis & Everh., J. Mycol. 5(3): 155. 1889.

Specimen examined: Canada, Quebec, leaf spot of *Populus deltoids* (Salicaceae), J. LeBoldus, CBS 130570.

***Sphaerulina oxyacanthae* (Kunze & J.C. Schmidt) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804414. Figs 29, 30.

Basionym: *Septoria oxyacanthae* Kunze & J.C. Schmidt, Myk. Hefte (Leipzig) 2: 108. 1823.

≡ *Phloeospora oxyacanthae* (Kunze & J.C. Schmidt) Wallr., Fl. Crypt. Germ. (Norimbergae) 2: 117. 1833.

Leaf spots amphigenous, medium to dark brown, subcircular to angular, 1–6 mm diam, with dark brown border. Conidiomata epiphyllous, up to 150 µm diam, brown, immersed, subepidermal, opening by irregular rupture of upper layer, with 3–4 apical flaps, exuding a long crystalline flame-like cirrus of conidia; wall 3–8 layers of brown *textura angularis*. On sterile *Carex* leaves on WA. Conidiophores reduced to conidiogenous cells, or with one supporting cell that can become fertile, forming a lateral conidiogenous locus just below the septum, 10–20 × 2.5–4 µm. Conidiogenous cells hyaline, smooth, aggregated, lining the inner cavity, terminal and lateral, ampulliform, 5–10 × 2.5–3.5 µm; proliferating several times percurrently near apex. Conidia hyaline, smooth, guttulate, 6–12-septate, falcate, widest in lower third of conidium, flexuous, apical cell tapering to subacute apex, forming a curved apical appendage-like elongation, 10–17 µm long, median cells are 5–10 µm long, basal cell forming an eccentric appendage that tapers to a subacutely rounded base, scar approximately 2–4

Fig. 29. Conidia and conidiogenous cells of *Sphaerulina oxyacanthae* (CBS 135098). Scale bars = 10 µm.

Fig. 30. *Sphaerulina oxyacanthae* (CBS 135098). A. Leaves with leaf spots. B. Close-up of conidiomata. C. Section through conidioma. D–F. Conidiogenous cells. G. Conidia (note appendages). Scale bars: C = 150 µm, all others = 10 µm.

µm below basal septum; basal cell (incl. appendage) 11–20 µm long, conidia (60–)75–90(–100) × 2(–2.5) µm.

Culture characteristics: Colonies on PDA umbonate with undulate edge and sparse, white aerial mycelium, surface isabelline, reverse greyish sepia, after 14 d, 3 cm diam; similar on MEA and PDA.

Specimen examined: Netherlands, Wageningen, 51°57'50.43"N 5°41'0.41"E, on leaves of *Crataegus* sp. (Rosaceae), Sep. 2012, W. Quaedvlieg (CBS H-21291, culture CBS 135098 = S654).

Notes: Several septoria-like species have been described from leaves of *Crataegus* (Farr & Rossman 2013). The present collection matches the description of *Septoria oxyacanthae* (leaf spots on *Crataegus oxyacantha* in Germany, conidia 8–12-septate; conidial dimensions not given). Unfortunately we have been unable to locate type material of this species.

***Sphaerulina patriniae* (Miura) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804415.

Basionym: *Septoria patriniae* Miura, Flora of Manchuria and East Mongolia, III Cryptogams, Fungi (Industr. Contr. S. Manch. Rly 27) 3: 465. 1928.

Specimen examined: South Korea, Pocheon, on leaves of *Patrinia scabiosaeifolia* (Valerianaceae), 20 Aug. 2006, H.D. Shin, KACC 42518 = CBS 128653.

***Sphaerulina populicola* (Peck) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804416.

Basionym: *Septoria populicola* Peck, Ann. Rep. N.Y. St. Mus. 40: 59. 1887.

= *Septoria populicola* House, Bull. N.Y. St. Mus.: 59. 1920. (nom. illegit.)
= *Mycosphaerella populicola* C.H. Thomps., Phytopathology 31: 251. 1941.

Specimen examined: USA, Washington, Puyallup, on *Populus trichocarpa* (Salicaceae), 2 May 1997, G. Newcombe, CBS 100042.

Fig. 31. Conidia, conidiogenous loci on a hypha, and conidiogenous cells of *Sphaerulina pseudovirgaureae* (CBS 135109). Scale bars = 10 µm.

***Sphaerulina pseudovirgaureae* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804417. Figs 31, 32.

Etymology: Named after its similarity to *Septoria virgaureae*.

Conidiomata pycnidial, separate, erumpent, globose, up to 120 µm diam, dark brown, exusing a creamy conidial cirrus through central ostiole, somewhat papillate; wall of 2–3 layers of brown textura angularis. Conidiophores reduced to conidiogenous cells or with one supporting cell, subcylindrical, 0–1-septate, branched below or not, pale brown at base, 10–20 × 3–5 µm. Conidiogenous cells integrated, hyaline, but pale brown at base, smooth, proliferating sympodially near apex, 7–17 × 2–3 µm. Conidia solitary, hyaline, smooth, guttulate, subcylindrical to narrowly obclavate, scolecosporous, irregularly curved, apex subobtuse, base truncate or narrowly obconically truncate, 3–10-septate, (30–)40–60(–80) × 2.5(–3) µm.

Culture characteristics: Colonies spreading, erumpent with sparse aerial mycelium and smooth, lobate margin and folded surface; reaching 13 mm diam after 2 wk. On MEA surface saffron with

Fig. 32. *Sphaerulina pseudovirgaureae* (CBS 135109). A. Conidiomata forming in culture. B. Conidiogenous cells. C. Microcyclic conidiation. D. Conidia. Scale bars = 10 µm.

patches of dirty white, reverse saffron to orange; on PDA surface and reverse saffron; on OA surface saffron.

Specimen examined: Netherlands, Nijmegen, de Duffelt, on leaves of *Solidago gigantea* (Asteraceae), Aug. 2012, S. Videira (**holotype** CBS H-21327, culture ex-type CBS 135109 = S669).

Notes: Several septoria-like species have been recorded on *Solidago* (Farr & Rossman 2013). Of these taxa *Sphaerulina pseudovirgaureae* is most similar to *Septoria virgureae* (conidia 80–100 × 1.5 µm) except that its conidia are shorter and wider.

***Sphaerulina quercicola* (Desm.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804419. Figs 33, 34.

= *Septoria quercina* Fautr., in Fautrey & Lambotte, Revue Mycol. 17: 170. 1895 (nom. illeg., art. 53; non Desmazières, 1847). Nom. nov. pro *Septoria quercicola* f. *macrospora* Roum., Revue Mycol. 13: 80. 1891.

Description in vivo. Symptoms definite, small hologenous leaf spots, scattered or in clusters, in the centre orange brown, pale yellowish brown to white, usually delimited by a blackened, somewhat elevated zone, the surrounding leaf tissues becoming red or yellow. Conidiomata pycnidial or acervuloid, one to a few in each leafspot, scattered, semi-immersed, predominantly hypophylloous, pale to dark brown, lenticular to globose, 100–200 µm diam; ostiolum often not well-developed, initially circular, central, soon opening widely, lacking distinctly differentiated cells; conidiomatal wall composed of *textura angularis* without distinctly differentiated layers and sometimes only well-developed in the lower part of the conidioma, mostly 10–15 µm thick, the outer cells with brown, somewhat thickened walls and 4.5–8 µm diam, the inner cells hyaline, thin-walled, 3–8 µm diam. Conidiogenous cells hyaline, discrete or integrated in simple, short, (1–)3–5-septate conidiophores which may be branched at the base, doliiiform, cylindrical, or ampuliform, hyaline, holoblastic, proliferating percurrently with one to several, more or less distinct annellations, or sympodially, sometimes both types of proliferation occurring in a single conidiogenous cell, 4.5–16(–22.5) × 3–4.5 µm. Conidia cylindrical, curved or flexuous, broadly rounded at the apex which is provided with a cap of mucilaginous material, attenuated

Fig. 33. Ascospores and asci of *Sphaerulina quercicola* (CBS 113266). Scale bar = 10 µm.

gradually to a broadly or more narrowly truncate base which often is also provided with an amorphous mass of mucilaginous material, hyaline, (0–)1–3-septate, constricted around the septa, sometimes at one or more septa also some amorphous mucilaginous material may be present, contents with numerous small oil droplets, (32.5–)38–50(–65) × 3–4 µm. Ascomata not clearly associated with leaf spots, pseudothecial, predominantly hypophylloous, black, subepidermal, erumpent to superficial, globose, 100–150 µm diam; apical ostiole 5–10 µm wide; wall consisting of 2–3 layers of medium brown *textura angularis*. Asci aparaphysate, fasciculate, bitunicate, subsessile, broadly ellipsoidal to subcylindrical, straight to slightly curved, 8-spored, 35–50 × 9–12 µm. Ascospores tri-

Fig. 34. *Sphaerulina quercicola* (CBS 663.94). A. Leaves with leaf spots. B. Close-up of lesion. C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Fig. 35. *Sphaerulina rhabdoclinis* (CBS 102195). A. Conidiomata forming in culture. B. Sporulation on PDA. C. Conidia. Scale bar = 10 µm.

multiseriate, overlapping, hyaline, guttulate, thin-walled, curved, rarely straight, fusoid-ellipsoidal with obtuse ends, widest at septum or just above, medianly 1-septate, not constricted at the septum, tapering towards both ends, (13–)15–18(–20) × (3.5–)4–4.5(–5) µm (av. 17 × 4.5 µm).

Culture characteristics: Colonies on OA reaching 5–7 mm diam in 21 d, with an even to undulating, colourless margin; colonies restricted, irregularly pustulate, immersed mycelium appearing dark greyish to olivaceous black, rosy buff near the margin, covered mostly with a dense mat of woolly, pure white or greyish aerial mycelium; reverse in the centre brown vinaceous or more greyish black, surrounded by brick to rosy buff. Pycnidia developing on the agar surface in the centre, releasing droplets of rosy-buff conidial slime. Colonies on MEA reaching 4–6(–8) mm diam in 21 d, with an even, to irregularly undulating margin which is mostly hidden under the aerial mycelium; colonies restricted, irregularly pustulate, the surface mostly blackish or very dark grey, covered by dense to diffuse, finely felted, white aerial mycelium; reverse mostly olivaceous black, near the margin cinnamon to buff. Numerous single and aggregated pycnidia developing on the colony surface in the centre, releasing milky white to rosy buff conidial slime. **Conidia as in planta** (CBS 663.94) though on average considerably longer, 51.5–74.5 × 3–4(–4.5) µm (OA), the apex, base and area around septa normally both provided with mucilaginous material as described above, (0–)1–3(–5)-septate.

Specimens examined: **Austria**, endophyte culture ex twig of *Quercus petraea* (Fagaceae), Aug. 1991, E. Halschläger 212 (H. A. van der Aa 10986), CBS 456.91. **France**, loc. unknown, on leaves of *Quercus* sp. ("divers Chênes"), distributed in

Desmazières, Pl. crypt. Fr., Fasc. 43, no. 2193 (PC, type of *Septoria incondita* var. *quercicola* Desm.). **Netherlands**, Utrecht, Baarn, on living leaves of *Q. robur*, 11 Aug. 1994, G. Verkley 225 (CBS H-21188), living culture CBS 663.94; prov. Utrecht, Soest, De Stompert, on living leaves of *Q. robur*, 15 Aug. 1995, G. ***Sphaerulina rhabdoclinis* (Butin) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804420. Fig. 35.

Basionym: *Dothistroma rhabdoclinis* Butin, For. Path. 30: 196. 2000.

Specimen examined: **Germany**, Wolfenbüttel, on needles of *Pseudotsuga menziesii* (Pinaceae), 24 May 1998, H. Butin, culture ex-type CBS 102195.

Note: *Sphaerulina rhabdoclinis* is phylogenetically closely related to *S. amelanchier*, which appears to be a species complex occurring on unrelated hosts (see Verkley et al. 2013).

***Sphaerulina viciae* Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov.** MycoBank MB804418. Figs 36, 37.

Etymology: Named after the host genus from which it was collected, *Vicia*.

On *Anthriscus* stem. Conidiomata pycnidial, solitary, erumpent, brown, globose, up to 150 µm diam, with central ostiole; wall of 3–6 layers of *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells lining the inner cavity, hyaline, smooth, subcylindrical, tapering and proliferating sympodially at apex, 5–10 × 3–4 µm. Conidia hyaline, smooth, guttulate, subcylindrical, irregularly curved, apex obtuse, base truncate, (3–)6–multiseptate, not or slightly constricted at septa (especially constricted on SNA, OA and MEA), (45–)55–75(–110) × (2.5–)3(–3.5) µm.

Culture characteristics: Colonies erumpent, spreading with folded surface and sparse aerial mycelium, and smooth, lobate margin; reaching 12 mm diam after 2 wk. On MEA and PDA surface and reverse olivaceous-grey. On OA surface pale olivaceous-grey.

Specimen examined: South Korea, on leaves of *Vicia amurensis* (Fabaceae), 12 Aug. 2004, H.D. Shin (holotype CBS H-21283, culture ex-type CPC 11414, 11416, 11415 = CBS 131898).

Notes: Several septoria-like species are known from *Vicia* (Farr & Rossman 2013). Of these, *Sphaerulina viciae* is most similar to *Septoria viceae* (conidia 30–60 × 2.5 µm), but distinct in having longer and wider conidia.

Clade 3: *Caryophylloseptoria*

Description: See Verkley et al. (2013)

Type species: *Caryophylloseptoria lychnidis* (Desm.) Verkley, Quaedvlieg & Crous.

Caryophylloseptoria pseudolychnidis Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804481. Fig. 38.

Etymology: Named after its morphological similarity to *Septoria lychnidis*.

Leaf spots on the upper leaf surface, scattered to confluent, distinct, circular, angular to irregular, usually very large, reaching up to 20 mm diam, often surrounded with yellow halo, lacking concentric rings, initially dark brown with pale green border, becoming brown to dark brown, finally turning greyish brown to pallid in the centre; on the lower leaf surface greyish brown to brown with yellowish margin (Shin & Sameva 2004). On sterile *Carex* leaves on WA. Conidiomata pycnidial, globose, up to 250 µm diam, black with central ostiole, but frequently splitting open at maturity, appearing acervular; wall of 6–8 layers of dark brown *textura angularis*. Conidiophores subcylindrical, lining the inner cavity, hyaline, smooth, reduced to conidiogenous cells, or with 1–2 supporting cells, frequently branched at base, 10–25 × 3–5 µm. Conidiogenous cells subcylindrical to ampulliform, 7–15 × 3–5 µm; proliferating sympodially or percurrently near apex. Conidia

Fig. 36. Conidia and conidiogenous cells of *Sphaerulina viciae* (CBS 131898). Scale bars = 10 µm.

Fig. 37. *Sphaerulina viciae* (CBS 131898). A. Conidiomata forming in culture. B, C, E. Conidiogenous cells. D, F. Conidia. Scale bars = 10 µm.

Fig. 38. *Caryophyllosporia pseudolychnidis* (CBS 128630). A. Colony sporulating on MEA. B. Vertical section through conidiomata. C, D. Conidiogenous cells. E. Conidia. Scale bar: B = 250 µm, others = 10 µm.

hyaline, smooth, guttulate, cylindrical, apex obtuse to subobtuse, base truncate, 3–3.5 µm; 1–3(–5)-septate, (25–)32–45(–50) × (2–)2.5–3(–3.5) µm.

Culture characteristics: Colonies on PDA flat, undulate, very sparse, mixed grey and white aerial mycelium, surface isabelline to fuscous-black, reverse olivaceous-black to isabelline for the younger tissue, after 14 d, 3 cm diam; on MEA umbonate, striate, undulate, surface fuscous-black to honey for the younger tissue after 14 d 3.5 cm diam; on OA surface dark-mouse-grey, reverse iron-grey to mouse-grey.

Specimen examined: South Korea, Yangpyeong, Jungmi mountain, on leaves of *Lychnis cognata* (Caryophyllaceae), 27 May 2007, H.D. Shin (holotype CBS H-21292, culture ex-type CBS 128630 = KACC 43866 = SMKC 23519).

Notes: Shin (1995) recorded this species for the first time in Korea, while Shin & Sameva (1999) provided a full morphological description. Although it compared well with the original description of this European taxon, its conidia tend to be smaller than those of *S. lychnidis* (50–70 × 2.5–3 µm), of which we have also examined European material (see Verkley et al. 2013, this issue).

Clade 4: pseudocercosporella-like

Note: See Frank et al. (2010).

Clade 5: Cercospora

Note: See Groenewald et al. (2013).

Clade 6: Phloeospora

Description: See above.

Type species: *P. ulmi* (Fr.) Wallr., Fl. Crypt. Germ. (Norimbergae) 2: 177. 1833.

***Phloeospora ulmi* (Fr.) Wallr.**, Fl. Crypt. Germ. (Norimbergae) 2: 177. 1833. Figs 39, 40.

≡ *Septoria ulmi* Fr. [as 'Septaria'], Novit. Fl. Svec. 5(cont.): 78. 1819.

Fig. 39. Conidia and conidiogenous cells of *Phloeospora ulmi* (CBS 613.81). Scale bars = 10 µm.

≡ *Septogloea ulmi* (Fr. & Kunze) Died., Krypt. Fl. Brandenburg (Leipzig) 9: 836. 1915.

≡ *Cylindrosporium ulmi* (Fr.) Vassiljevsky, Fungi Imperfecti Parasitici 2: 580. 1950.

= *Mycosphaerella ulmi* Kleb., Z. PflKrankh. 12: 257. 1902.

= *Sphaerella ulmi* (Kleb.) Sacc. & D. Sacc., Syll. Fung. (Abellini) 17: 642. 1905.

Leaf spots angular, vein limited, separate, becoming somewhat confluent, initially small yellow-green spots that finally turn brown. **Conidiomata** acervular, hypophylloous, separate, subepidermal, composed of thin-walled, medium brown *textura angularis*, up to 200 µm diam, opening by irregular rupture, and exuding a prominent cirrus of orange to yellow-orange conidia. **Conidiophores** reduced to conidiogenous cells, or with 1–2 supporting cells, branched below or not, subcylindrical, 10–30 × 4–5 µm. **Conidiogenous cells** hyaline, smooth, subcylindrical, straight to once geniculate, with numerous prominent percurrent proliferations at apex, 10–15 × 4–5 µm. **Conidia** solitary, hyaline, smooth, straight to curved, guttulate or not, fusiform, tapering towards an obtuse or subobtuse apex, and truncate base, 2–3 µm diam, with minute marginal frill,

Fig. 40. *Phloeospora ulmi* (CBS 613.81). A, B, D, E. Conidiomata bursting through host tissue. G, H. Microconidiogenous cells. K. Spermatia. C, F, I, J, L. Macroconidiogenous cells (arrows denote percurrent proliferation). M. Conidia. Scale bars = 10 µm.

3–5-septate, (20–)30–50(–60) × (3.5–)4–5(–6) µm. Leaf spots also contain black spermatogonia and ascomata.

Specimens examined: **Austria**, Innsbruck, near Hungerburg, on leaves of *Ulmus* sp. (*Ulmaceae*), 21 Sep. 1981, H.A. van der Aa, CBS H-14740, H-14861, culture CBS 613.81; Innsbruck, road to Hungerburg, on leaves of *Ulmus glabra*, 20 Oct. 1996, W. Gams, CBS 344.97. **Netherlands**, Baarn, garden of CBS, Oosterstraat 1, on leaves of *Ulmus* sp., 26 Aug. 1998, H.A. van der Aa, CBS H-14739, culture CBS 101564. **Unknown**, on leaves of *Ulmus pedunculata*, 15 Jul. 1901, A. van Luijk, CBS H-920.

Note: Distinct from *Septoria* s. str. by having acervuli, and conidiogenous cells with prominent percurrent proliferation.

Clade 7: septoria-like

Septoria gladioli Pass., in Rabenhorst, Fungi europ. exsicc.: no. 1956. 1875. Passerini, Atti Soc. crittog. ital. 2: 41. 1879.

Description in vitro (18 °C, NUV). CBS 121.20: Colonies on OA 15–18 mm diam after 21 d, with an even to slightly ruffled, colourless margin; colonies plane, immersed mycelium olivaceous black, fading over amber towards the margin, aerial mycelium absent;

reverse concolorous. No sporulation observed. Colonies on MEA 10–15 mm diam after 21 d, with an even, pale luteous to amber margin; colonies restricted, irregularly pustulate to cerebriform, immersed mycelium ochreous to salmon, covered by diffuse, finely felted, white aerial mycelium; reverse in the centre rust, fading towards the margin over apricot to pale luteous. No sporulation observed. CBS 353.29: Colonies on OA 16–20 mm diam after 21 d, with an even to slightly ruffled, colourless margin; colonies plane, immersed mycelium rosy buff mixed with some olivaceous grey, aerial mycelium absent; reverse mainly pale purplish grey to pale mouse grey. No sporulation observed. Colonies on MEA 14–22(–26) mm diam after 21 d, with an even to lobed, buff margin; colonies restricted, elevated towards the centre, radially striate, immersed mycelium greenish olivaceous fading to ochreous or buff salmon, the central part mostly covered by diffuse, finely felted, white aerial mycelium; reverse in the centre dark brick to isabelline or hazel, fading towards the margin over pale cinnamon to buff. No sporulation observed.

Specimen examined: **Netherlands**, Mar. 1929, J.C. Went, CBS 353.29. Unknown location and host, 1920, W.J. Kaiser, CBS 121.20.

Notes: Priest (2006) provided a complete description of *S. gladioli* on host material, based on observations of an isotype in MEL, and several specimens on *Gladiolus* cultivars collected in Australia. The two strains available from the CBS are old and sterile, and show some differences that also seem to be reflected in the DNA data obtained. *Septoria gladioli* is the only species of septorioid fungi described from the genus *Gladiolus*. An unusual feature of the species is that it overwinters as “sclerotia”, that cause leaf infections in the next season (Priest 2006). The conidiogenous cells are holoblastic and very distinctly proliferate percurrently to form subsequent conidia, but no sympodial proliferation has been reported. Based on the multilocus phylogeny, the aforementioned isolates should be placed in their own genus, with the genus *Phloeospora* as its closest relative. Recollecting material will be required to determine the generic disposition, the delimitation of the taxa (as there seem to be at least two) and to which of these taxa the name *Septoria gladioli* should be applied.

Clade 8: passalora-like

Passalora dioscoreae (Ellis & G. Martin) U. Braun & Crous, in Crous & Braun, CBS Biodiversity Ser. (Utrecht) 1: 162. 2003.

Specimen examined: South Korea, on leaves of *Dioscorea tokoro* (Dioscoreaceae), 24 Oct. 2003, H.D. Shin (CPC 10855); *ibid.*, on leaves of *Dioscorea tenuipes*, 1 Jan. 2004, H.D. Shin (CPC 11513).

Notes: *Passalora dioscoreae* is not congeneric with the type species of the genus, *P. bacilligera*. The taxonomy of *Passalora* and its relatives will be treated in a future publication (Videira et al., in prep.).

Clade 9: Neoseptoria

Neoseptoria Quaedvlieg, Verkley & Crous, gen. nov.
Mycobank MB804421.

Etymology: Resembling the genus *Septoria*.

Folioicolous. Conidiomata black, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding creamy conidial

mass; wall of 2–3 layers of brown *textura angularis*. Conidiophores 0–2-septate, subcylindrical, hyaline to pale brown at base, smooth, straight to geniculate-sinuous. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, subcylindrical to ampulliform, straight to geniculate-sinuous; proliferating several times percurrently near apex, rarely sympodially. Conidia scolecosporous, hyaline, smooth, flexuous, rarely straight, granular, thin-walled, narrowly obclavate, apex subobtuse, base long obconically truncate, tapering to a truncate hilum, 3–multiseptate.

Type species: *Neoseptoria caricis* Quaedvlieg, Verkley & Crous.

Note: The genus *Neoseptoria* is morphologically similar to *Septoria*, but distinct in having mono- to polyphialidic conidiogenous cells that proliferate percurrently at the apex.

Neoseptoria caricis Quaedvlieg, Verkley & Crous, sp. nov.
Mycobank MB804422. Figs 41, 42.

Etymology: Named after the host genus on which it occurs, *Carex*.

Fig. 41. Conidia and conidiogenous cells of *Neoseptoria caricis* (CBS 135097). Scale bars = 10 µm.

Fig. 42. *Neoseptoria caricis* (CBS 135097). A, B. Conidiomata developing in culture. C, D. Conidiogenous cells. E, F. Conidia. Scale bars = 10 µm.

On sterile Carex leaves on WA. Conidiomata up to 150 µm diam, black, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding creamy conidial mass; wall of 2–3 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells, or 0–2-septate, subcylindrical, hyaline to pale brown at base, smooth, straight to geniculate-sinuous, 10–30 × 2.5–3.5 µm. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, subcylindrical to ampulliform, straight to geniculate-sinuous, 8–15 × 2.5–3 µm; proliferating several times percurrently near apex, rarely sympodially. Conidia scolocosporous, hyaline, smooth, flexuous, rarely straight, granular, thin-walled, narrowly obclavate, apex subobtuse, base long obconically truncate, tapering to a truncate hilum, 1.5–2 µm diam, 3(–5)-septate, (40–)55–68(–80) × (2.5–)3(–3.5) µm.

Culture characteristics: Colonies on PDA erumpent, undulate, lacking aerial mycelium, reverse iron-grey, after 14 d, 3 cm diam; on MEA reverse greyish sepia, after 14 d, 3 cm diam, with fine, pale pink to orange aerial mycelium; on OA similar to MEA, but with pinkish tufts of aerial mycelium.

Specimen examined: Netherlands, Wageningen, on leaves of *Carex acutiformis* (Cyperaceae), Aug. 2012, W. Quaedvlieg (holotype CBS H-21293, culture ex-type CBS 135097 = S653).

Notes: Several septoria-like species have been described from Carex (Farr & Rossman 2013). Of these, *N. caricis* is most similar to *S. caricicola* (conidia 25–55 × 4 µm; (6–)7(–8)-septate), but distinct in having longer and narrower conidia with less septa.

Clade 10: *Pseudocercospora*

Note: See Crous et al. (2013)

Clade 11: *Zymoseptoria*

Note: See Quaedvlieg et al. (2011).

Clade 12: *Ramularia*

Note: See Crous et al. (2009a, c).

Clade 13: *Dothistroma*

Note: See Barnes et al. (2004).

Clade 14: *Stromatoseptoria*

Stromatoseptoria Quaedvlieg, Verkley & Crous, gen. nov. MycoBank MB804423.

Etymology: Stroma = referring to central stoma in pycnidium that gives rise to conidiophores; Septoria = septoria-like morphology.

Foliicolous, plant pathogenic. Conidiomata pycnidial, hypophyllous, subglobose to lenticular, very pale brown to dark brown, immersed to erumpent, exuding conidia in white cirrus; ostiolum central, circular, surrounding cells concolorous; conidiomatal wall composed of a homogenous tissue of hyaline to very pale brown, angular to irregular cells. Conidiophores subcylindrical, branched, hyaline, septate. Conidiogenous cells hyaline, discrete or integrated, cylindrical or narrowly ampulliform, holoblastic, often also proliferating percurrently. Conidia cylindrical, slightly to distinctly curved, broadly rounded apex, attenuated towards a truncate base, transversely euseptate, mostly constricted at septa.

Type species: *Stromatoseptoria castaneicola* (Desm.) Quaedvlieg, Verkley & Crous.

Notes: *Stromatoseptoria* is distinguished from *Septoria* based on the central cushion or stroma that gives rise to its conidiophores (*sensu* *Coniella* and *Pilidiella*; van Niekerk et al. 2004), and conidia that tend to be olivaceous-brown in mass, and also turn olivaceous and verruculose with age.

***Stromatoseptoria castaneicola* (Desm.)** Quaedvlieg, Verkley & Crous, comb. nov. MycoBank MB804424. Fig. 43. *Basionym:* *Septoria castaneicola* Desm., Ann. Sci. Nat., Sér. 3, Bot. 8: 26. 1847.

≡ (?) *Phleospora castanicola* (Desm.) D. Sacc., Mycoth. Ital., Cent. 1-2, no. 173.

= *Septoria gilletiana* Sacc., Michelia 1: 359. 1878.

? = *Septoria castaneae* Lév., Ann. Sci. Nat., Sér. 3, Bot. 5: 278. 1846.

≡ *Cylindrosporium castaneae* Krenner, Bot. Közl. 41(3-4): 126. 1944.

Description *in vivo*: Leaf spots numerous, small, angular, and often merging to irregular patterns, visible on both sides of the leaf, initially pale yellowish brown, later reddish brown with a narrow, darker border; Conidiomata pycnidial, hypophyllous, several in each

Fig. 43. *Stromatoseptoria castaneicola* (CBS 102320). A. Colony sporulating on MEA. B. Stroma giving rise to conidiogenous cells. C, D. Conidiogenous cells. E. Conidia. Scale bars: B = 200 µm, all others = 10 µm.

leaf spot, subglobose to lenticular, very pale brown to dark brown, usually fully immersed, 80–150(–200) µm diam, releasing conidia in white cirri; *ostiolum* not well-differentiated, central, circular, 18–50 µm wide, surrounding cells concolorous; *conidiomatal wall* about 10–17 µm thick, composed of a homogenous tissue of hyaline to very pale brown, angular to irregular cells 4–10 µm diam; *Conidiophores* subcylindrical, branched at base, hyaline, smooth, 1–2-septate; base frequently brown, verruculose. *Conidiogenous cells* hyaline, discrete or integrated in conidiophores cylindrical or narrowly ampulliform, holoblastic, often also proliferating percurrently with up to 3 closely positioned annellations, 7–17(–20) × 3–4(–5) µm. *Conidia* cylindrical, slightly to distinctly curved, irregularly bent or flexuous, with a relatively broadly rounded apex, attenuated towards a truncate base, basal and apical cell often both wider than intermediate cells, (0–)2–3(–4)-septate, mostly constricted around the septa in the living state, hyaline, contents with several oil-droplets and granular material in each cell in the living state, with granular contents in the rehydrated state, 30–46 × 3–4 µm ("T"; rehydrated, "NT" 2–3 µm wide). Conidia are olivaceous-brown in mass, and older conidia also turn olivaceous and verruculose, and at times anastomose in culture.

Culture characteristics: Colonies (CBS 102322) on OA reaching 4–8 mm diam in 25 d (9–12 mm in 33 d), with an even, glabrous, buff margin; colonies restricted, up to 1 mm high, immersed mycelium homogeneously buff, where conidiomatal complexes develop dark brick to black, in part covered by pure white, dense, appressed and woolly aerial mycelium, later a salmon haze occurs in the immersed mycelium; reverse buff, locally cinnamon to sepia. Colonies on CMA reaching (4–)7–11 mm diam in 25 d (8–12 mm in 33 d), as on OA, but with a halo of reddish to salmon, diffusing pigment, which becomes more intense after 33 d, and immersed mycelium in the centre darker, and aerial mycelium more strongly developed, later becoming locally salmon or citrine; reverse brick and dark brick, surrounded by a reddish to salmon zone. Colonies on MEA reaching 6.5–9 mm diam in 25 d (9–11.5 mm in 33 d), with an even, buff to cinnamon margin, entirely hidden under the aerial mycelium, with a very faint halo of diffusing pigment; colonies restricted, up to 4 mm high, hemispherical to irregularly pustulate, entirely covered by a dense mat of felted aerial mycelium, which, especially in the centre, attains a rosy buff or primrose to citrine haze; reverse cinnamon to hazel, around a brick to dark brick centre. Colonies on CHA reaching 7–9 mm diam in 25 d (9–11 mm in 33 d), as on MEA, but no diffusing pigment observed around the colonies. *Conidiomata* on OA developing after 10–15 d, black, globose, single or merged to complexes up to 250 µm diam, releasing milky white conidial slime. *Conidiogenous cells* as *in planta*. *Conidia* as *in planta*, mostly 3-septate, 30–45 × 3.5–4.5 µm (CBS 102320, OA, "T"; "NT" 3 µm wide).

Specimens examined: **Austria**, Tirol, Klausen, on leaves of *Castanea vesca* (Fagaceae), Aug., distributed in F. von Höhnel, Krypt. exsicc. no. 415, (PC0084576, PC0084583). **France**, Lébisey, Aug. and Sep. 1843, M. Roberge, 'Coll. Desmazières 1863, no. 8', on leaves of *Castanea sativa* (PC0084574, type of *Septoria castanicola* Desm.); same substr., Meudon, 1 Aug. 1849 (PC0084571, PC0084589, PC0084590, PC0084591) and Jul. 1852 (PC0084572); same substr., loc. and date unknown, 'Coll. Desmazières 1863, no. 8' (PC0084570); Seine-et-Marne, Fontainebleau, Sep 1881, distributed in Roumeguère, Fungi Gallici exsicc. no. 2029 (PC0084575). **Netherlands**, prov. Utrecht, Baarn, Lage Vuursche, on living leaves of *Castanea sativa*, 29 Aug. 1999, G. Verkley 912 (CBS H-21200), cultures CBS 102320–102322; same substr., prov. Limburg, St. Jansberg, 9 Sep. 1999, G. Verkley 932 (CBS H-21214), culture CBS 102377; same substr., prov. Limburg, Molenhoek, Heumense Schans (46-12-55), 23 Aug. 2004, G. Verkley & M. Starink 3040, culture CBS 116464.

Notes: According to the original diagnosis that Desmazières published in 1847 based on material on *Castanea* collected in autumn, the conidia are elongated, thin and curved, and about 40 µm in length. No further details like conidial septa were given. The material PC0084574 is the only collection received from PC that antedates the publication and assumedly is the type. It consists of several leaves with numerous pycnidia in leaf spots, some of which belong to *Septoria castaneicola* with the characteristic conidia, but most are a spermatial state of most likely the *Mycosphaerella punctiformis* complex (= *Ramularia*, Verkley et al. 2004).

Teterevnikova-Babayan (1987) treated *S. castaneicola* Desm. as a synonym of *S. castaneae* Lév., and both originally were described from the same host, *Castanea sativa* (syn. *C. vesca*). Teterevnikova-Babayan (1987) described the conidia as 3-septate, 25–40 × 2.5–4.5 µm, which is in fairly good agreement with present observations. The type of *S. castaneae* Lév. could not be studied and the name remains doubtful. Even though Léveillé described symptoms that match those of *S. castaneicola* fairly well, he described the conidia as aseptate, and failed to give information about their size.

Clade 15: *Lecanosticta*

Note: See Quaedvlieg et al. (2012).

Clade 16: *Phaeophleospora*

Note: See Crous et al. (2009b, c).

Clade 17: *Cytostagonospora*

Type species: *Cytostagonospora photiniicola* Bubák [as "photinicola"], Ann. Mycol. 14: 150. 1916.

Description: See above.

Type species: *Cytostagonospora photiniicola* Bubák [as "photinicola"], Ann. Mycol. 14: 150. 1916.

***Cytostagonospora martiniana* (Sacc.) B. Sutton & H.J. Swart, Trans. Br. mycol. Soc. 87: 99. 1986. Figs 44, 45.**

Basionym: *Septoria martiniana* Sacc., Syll. Fung. (Abellini) 10: 351. 1892.

= *Septoria phyllodiorum* Cooke & Massee, Grevillea 19(90): 47. 1890, non *S. phyllodiorum* Sacc., Hedwigia 29: 156. 1890.

On sterile Carex leaves on WA. Leaf spots amphigenous, circular, grey to brown with raised dark brown border, 1–3 mm diam. *Conidiomata* immersed, subepidermal, epiphyllous, solitary to aggregated with stromatic tissue, with central ostiolar opening exuding a creamy to white conidial mass, rupturing at maturity (pycnidial to acervular), brown, globose, up to 400 µm diam; wall of 3–6 layers of brown *textura angularis*. *Conidiophores* hyaline, smooth, subcylindrical, 0–5-septate, branched or not, 10–15(–50) × 3–4 µm, giving rise to terminal and lateral conidiogenous cells. *Conidiogenous cells* hyaline, smooth, subcylindrical or ampulliform, 4–8 × 3–4 µm, polyphialidic, with apical and lateral loci, with visible periclinal thickening, at times also proliferating percurrently (both modes can also be present on the same conidiogenous cell). *Conidia* hyaline, smooth, granular, irregularly curved, subcylindrical

to narrowly obclavate, apex subobtuse, base long, obconically truncate, (1–)3–32–45(–50) × (1.5–)2(–3) µm; base not thickened, 0.5–1 µm diam.

Culture characteristics: Colonies on PDA convex, erumpent with feathery margin, lacking aerial mycelium, surface fuscous-black, reverse olivaceous-black, after 14 d, 4 cm diam, with a beautiful purple exudate at the outer edges; on MEA, after 14 d, 3.5 cm diam, lacking any exudate; on OA surface fuscous-black, reverse olivaceous-grey, after 14 d, 4 cm diam, purplish-red coloured exudate.

Specimen examined: Australia, Warneet close to Melbourne, S38°13'37.8" E145°18'25.4", on leaves of *Acacia pycnantha* (Mimosaceae), 21 Oct. 2009, P.W. Crous (specimen CBS H-21297, culture CBS 135102 = CPC 17727).

Notes: The present collection matches the description of *Cystostagonospora martiniana* provided by Sutton & Swart (1986). As discussed by the authors, this genus is distinct from *Septoria* s. str. based on its conidiomata aggregated in stromatic tissue, and unique mode of conidiogenesis. In culture conidiogenous cells exhibited a mixture of sympodial proliferation, or were polyphialidic with periclinal thickening, but also proliferated percurrently. Species of *Septoria* occurring on *Acacia* were treated by Sutton & Pascoe (1987).

Clade 18: *Zasmidium*

Note: See Crous et al. (2007a, b, 2009c).

Clade 19: *Polyphialoseptoria*

Polyphialoseptoria Quaedvlieg, R.W. Barreto, Verkley & Crous, gen. nov. MycoBank MB804425.

Etymology: Polyphialo = polyphialides; *Septoria* = septoria-like.

Foliicolous, plant pathogenic. Conidiomata brown, erumpent, pycnidial (acervular in culture), globose, brown; wall of 3–6 layers of pale brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells hyaline, smooth, subcylindrical to ampulliform; proliferating sympodially at apex, forming polyphialides with minute periclinal thickening, or as solitary loci on superficial mycelium in culture. Conidia hyaline, smooth, granular to guttulate, sclecosporous, irregularly curved, apex subobtuse, base long obconically truncate, transversely multi-euseptate, in older cultures disarticulating at septa; microcyclic conidiation also common in older cultures.

Type species: *Polyphialoseptoria terminaliae* Quaedvlieg, R.W. Barreto, Verkley & Crous.

Fig. 44. Conidia and conidiogenous cells of *Cystostagonospora martiniana* (CBS 135102). Scale bars = 10 µm.

Fig. 45. *Cystostagonospora martiniana* (CBS 135102). A. Leaf spot. B. Conidiomata forming in culture. C–F. Conidiogenous cells. G. Conidia. Scale bars = 10 µm.

Polyphialoseptoria tabebuiae-serratifoliae Quaedvlieg, Alfenas & Crous, sp. nov. MycoBank MB804427. Figs 46, 47.

Etymology: Named after its host, *Tabebuia serratifolia*.

Leaf spots variable in number on mature leaves; initially as small spots or purple-brown areas, with the inner part becoming grey-white with age, surrounded by a purple-brown halo. **Conidiomata** developing on sterile barley leaves on WA, pale cream in colour, erumpent, globose, up to 180 µm diam; wall of 2–3 layers of pale brown *textura angularis*. **Conidiophores** hyaline, smooth, cylindrical, septate, branched, 10–35 × 1.5 µm. **Conidiogenous cells** terminal and lateral, cylindrical, hyaline, smooth, proliferating sympodially, 10–15 × 1.5 µm. **Conidia** solitary, hyaline, smooth, granular, irregularly curved, subcylindrical, apex subobtuse, base truncate, (0–)1–3(–4)-septate, (15–)25–35(–55) × 1.5(–2) µm.

Culture characteristics: Colonies flat, spreading, with sparse aerial mycelium and smooth, even margins, reaching 40 mm diam after 2 wk. On OA surface dirty pink; on PDA surface and reverse dirty white. On MEA surface folded, dirty white, reverse cinnamon.

Specimen examined: Brazil, Minas Gerais, Viçosa, on leaves of *Tabebuia serratifolia* (Bignoniaceae), 1999, A.C. Alfenas (**holotype** CBS H-21299, culture ex-type CBS 112650).

Notes: Inácio & Dianese (1998) described *Septoria tabebuiae-impetiginosae* on *T. impetiginosa* (conidia 25–67 × 2–4 µm, 2–6-septate), and also compared this species to *S. tabebuiae* (18–40 × 1.7–2.5 µm, aseptate conidia) on *T. berteroii*, and *S. cicutana* (34–40 × 0.8–1 µm) on *T. pentaphylla* and *T. spectabilis*. Furthermore, they also referred to an undescribed species Ferreira (1989) mentioned on *T. serratifolia* in Viçosa, Minas Gerais, which is named as *S. tabebuiae-serratifoliae* in the present study.

Fig. 46. Conidia and conidiogenous loci on hypha of *Polyphialoseptoria tabebuiae-serratifoliae* (CBS 112650). Scale bars = 10 µm.

Fig. 47. *Polyphialoseptoria tabebuiae-serratifoliae* (CBS 112650). A. Conidiomata forming in culture. B. Conidiogenous cells. C. Conidia. Scale bars = 10 µm.

Polyphialoseptoria tabebuiae-serratifoliae is distinct from species of *Septoria* known from *Tabebuia* based on its conidial morphology.

Polyphialoseptoria terminaliae Quaedvlieg, R.W. Barreto, Verkley & Crous, sp. nov. MycoBank MB804426. Fig. 48.

Etymology: Named after the host genus from which it was collected, *Terminalia*.

Leaf spots irregular to subcircular, amphigenous, mostly aggregated along leaf veins, pale brown, 3–8 mm diam, surrounded by a prominent, wide, red-purple border. On sterile *Carex* leaves on WA. **Conidiomata** brown, erumpent, pycnidial (acervular in culture), up to 600 µm diam, globose, brown, exuding a crystalline cirrus of conidia; wall of 3–6 layers of pale brown *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Conidiogenous cells** hyaline, smooth, subcylindrical to ampulliform, 5–10 × 3–4 µm; proliferating sympodially at apex, forming polyphialides with minute periclinal thickening, or as solitary loci on superficial mycelium in culture. **Conidia** hyaline, smooth, granular to guttulate, scolecosporous, irregularly curved, apex subobtuse, base long obconically truncate (1–1.5 µm diam), multisepitate (–16), in older cultures disarticulating at septa; microcyclic conidiation also common in older cultures, (40–)75–120(–140) × 2–3(–3.5) µm.

Culture characteristics: Colonies on PDA erumpent with feathery margin, lacking aerial mycelium, surface fuscous-black, reverse olivaceous-black to buff in the younger tissue, after 14 d, 1 cm diam; on MEA surface and reverse isabelline to greyish-sepia; on OA surface pale-vinaceous, reverse rosy-buff to buff.

Specimen examined: Brazil, Minas Gerais, Viçosa, on leaves of *Terminalia catappa* (Combreteaceae), 18 May 2010, R.W. Barreto (**holotype** CBS H-21298, culture ex-type CBS 135106 = CPC 19611; ibid., (CBS 135475 = CPC 19487)

Notes: As far as we could establish there are presently no species of *Septoria* described from *Terminalia*, and as this taxon is distinct from all taxa in GenBank, we herewith describe it as a novel species. A *Septoria* sp. has been reported on leaves of *Terminalia* sp. in Florida and Venezuela (Farr & Rossman 2013). *Polyphialoseptoria* is distinct from *Septoria* based on the presence of polyphialides. *Neoseptoria* also has phialides as observed in *Polyphialoseptoria*, but these tend to chiefly be monopodialides.

Clade 20: *Ruptoseptoria*

Ruptoseptoria Quaedvlieg, Verkley & Crous, gen. nov. MycoBank MB804428.

Fig. 48. *Polyphialoseptoria terminaliae* (CBS 135106). A. Leaves with leaf spots. B, C. Conidiomata sporulating in culture. D–F. Conidiogenous cells and loci. G. Conidia. Scale bars = 10 µm.

Etymology: Rupto = irregular rupture of conidiomata; *Septoria* = septoria-like.

Foliicolous, plant pathogenic. *Conidiomata* black, appressed, elongated, pycnidial, but opening via irregular rupture, convulated; exuding a creamy white conidial mass; outer wall dark brown, crusty, consisting of 6–8 layers of dark brown *textura angularis*; giving rise to 2–3 inner layers of pale brown to hyaline *textura angularis*. *Conidiophores* lining the inner cavity, hyaline, smooth or pale brown, verruculose at base, branched below, septate, subcylindrical. *Conidiogenous cells* integrated, terminal, subcylindrical, smooth; proliferating sympodially at apex, or apex phialidic with minute periclinal thickening. *Conidia* solitary, hyaline, smooth, guttulate, subcylindrical to narrowly obclavate, gently to irregularly curved, apex subobtuse, base truncate to narrowly ovoid, transversely septate.

Type species: *Ruptoseptoria unedonis* (Roberge ex Desm.) Quaedvlieg, Verkley & Crous.

Ruptoseptoria unedonis (Roberge ex Desm.) Quaedvlieg, Verkley & Crous, **comb. nov.** MycoBank MB804429. Figs 49, 50.

Basionym: *Septoria unedonis* Roberge ex Desm., Ann. Sci. Nat., Bot., Sér. 3(8): 20. 1847.

= *Sphaerella arbuticola* Peck, Bull. Torrey Bot. Club 10(7): 75. 1883.

≡ *Mycosphaerella arbuticola* (Peck) Jaap, Ann. Mycol. 14(1/2): 13. 1916.

≡ *Mycosphaerella arbuticola* (Peck) House, Contr. Univ. Mich. Herb. 9(8): 587. 1972.

Leaf spots numerous, small, amphigenous, irregular to subcircular, whitish in the middle, with very broad, purple borders. *Conidiomata* black, appressed, elongated, pycnidial, but opening via irregular rupture, convulated, up to 450 µm diam, exuding a creamy white conidial mass; outer wall dark brown, crusty, consisting of 6–8 layers of dark brown *textura angularis*; giving rise to 2–3 inner

Fig. 49. Conidia and conidiogenous cells of *Ruptoseptoria unedonis* (CBS 355.86). Scale bars = 10 µm.

layers of pale brown to hyaline *textura angularis*. *Conidiophores* lining the inner cavity, hyaline, smooth or pale brown, verruculose at base, branched below, 1–2-septate, subcylindrical, 10–15 × 2–4 µm. *Conidiogenous cells* integrated, terminal, subcylindrical, smooth, 6–12 × 2.5–3.5 µm; proliferating sympodially at apex, or apex phialidic with minute periclinal thickening. *Conidia* solitary, hyaline, smooth, guttulate, subcylindrical to narrowly obclavate, gently to irregularly curved, apex subobtuse, base truncate to narrowly ovoid, 1–3(–6)-septate, (25–)30–47(–56) × 2(–3) um.

Fig. 50. *Ruptoseptoria unedonis* (CBS 355.86). A, C. Conidiomata forming in culture. B, D. Conidiogenous cells. E. Conidia. Scale bars: A = 450 µm, C = 110 µm, all others = 10 µm.

Culture characteristics: Colonies on OA spreading with moderate aerial mycelium and smooth, even margins; surface olivaceous-grey in outer region, centre dirty white to pale pink, reverse iron grey; on MEA surface dark-mouse-grey to mouse-grey, reverse greenish-black; on PDA surface mouse-grey to dark-mouse-grey, reverse greenish-black.

Specimen examined: France, Seignosse le Penon, Landes, Forest communale de Seignosse, on leaves of *Arbutus unedo* (Ericaceae), Aug. 1986, H.A. van der Aa (CBS H-14645, culture CBS 355.86).

Notes: *Mycosphaerella arbuticola* (CBS 355.86) is a species pathogenic to *Arbutus menziesii* in California (Aptroot 2006), clusters with “*Septoria*” *unedonis* (CBS 755.70, CBS H-18192), which is associated with leaf spots on *Arbutus unedo* in Croatia, and elsewhere in Europe. Based on these results, the sexual-aseexual link between these two names is confirmed. Morphologically, however, *Ruptoseptoria* is similar to *Septoria*, and can only be distinguished based on its conidiomata that are convoluted, opening by irregular rupture, and conidiogenous cells that are frequently phialidic.

Clade 21: *Dissoconium* (*Dissoconiaceae*)

Note: See Li et al. (2012).

Clade 22: *Readeriella* (*Teratosphaeriaceae*)

Note: See Crous et al. (2007a, 2009a–c).

Clade 23: *Teratosphaeria*

Note: See Crous et al. (2007, 2009c).

Clade 24: *septoria-like*

Specimen examined: Brazil, Nova Friburgo, on leaves of *Tibouchina herbacea* (Melastomataceae), 15 Dec. 2007, D.F. Parreira (CBS 134910 = CPC 19500).

Note: The taxonomy of this species could not be resolved, as isolate CPC 19500 proved to be sterile.

Clade 25: *Cylindroseptoria*

***Cylindroseptoria* Quaedvlieg, Verkley & Crous, gen. nov.** MycoBank MB804430.

Etymology: Cylindro = cylindrical conidia; Septoria = septoria-like.

Conidiomata pycnidial with central ostiole, or cupulate, separate, brown, short-stipitate, tapering towards base; rim with elongated brown, thick-walled cells with obtuse ends; rim covered with mucoid layer that flows over from conidiomatal cavity, filled with conidial mass; wall of 3–4 layers of medium brown *textura angularis*, becoming hyaline towards inner region. **Conidiogenous cells** hyaline, smooth, ampulliform, lining inner cavity, with prominent periclinal thickening at apex. **Conidia** solitary, hyaline, smooth, granular or not, cylindrical with obtuse apex, tapering at base to truncate scar, aseptate.

Type species: *Cylindroseptoria ceratoniae* Quaedvlieg, Verkley & Crous.

***Cylindroseptoria ceratoniae* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804431. Figs 51, 52.

Etymology: Named after the host genus on which it occurs, *Ceratonia*.

Conidiomata separate, brown, cupulate, short-stipitate, rim up to 300 µm diam, 100–180 µm tall, tapering towards base, 20–50 µm diam (on *Anthriscus sylvestris* stems, not on OA or PDA, where they appear more flattened with agar surface); rim with elongated brown, thick-walled cells with obtuse ends, 5–12 × 4–5 µm; rim covered with mucoid layer that flows over from conidiomatal cavity, filled with conidial mass; wall of 3–4 layers of medium brown *textura angularis*, becoming hyaline towards inner region. **Conidiogenous cells** hyaline, smooth, ampulliform, lining inner cavity, 7–12 × 4–6 µm; apex 2 µm diam, with prominent periclinal thickening. **Conidia** solitary, hyaline, smooth, granular or not, cylindrical with obtuse

apex, tapering at base to truncate scar 1 µm diam, aseptate, (10–12–14(–16) × 3(–3.5) µm.

Culture characteristics: Colonies spreading, reaching 28 mm diam after 2 wk, with sparse aerial mycelium and even, lobate margins. On MEA surface iron-grey, reverse olivaceous-grey. On OA surface olivaceous-grey. On PDA surface and reverse iron-grey.

Specimen examined: Spain, Mallorca, Can Pastilla, on leaves of *Ceratonia siliqua* (Caesalpinaeae), 24 May 1969, H.A. van der Aa (**holotype** CBS H-21300, culture ex-type CBS 477.69).

Notes: *Cylindroseptoria ceratoniae* is quite distinct in that it has cup-shaped acervuli, ampilliform conidiogenous cells with periclinal thickening, and hyaline, aseptate, cylindrical conidia. *Cylindroseptoria* needs to be compared with *Satchmopsis* (infundibular conidiomata), *Cornucopiella* (tubular conidiomata) and *Thaptospora* (cylindrical / lageniform / campanulate conidiomata), but the combination of cupulate conidiomata and cylindrical, and aseptate conidia is distinct.

***Cylindroseptoria pistaciae* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804432. Figs 53, 54.

Etymology: Named after the host genus on which it occurs, *Pistacia*.

Fig. 51. Conidia and conidiogenous cells of *Cylindroseptoria ceratoniae* (CBS 477.69). Scale bar = 10 µm.

Cylindroseptoria pycnidial, erumpent, globose, black, separate, with black crusty outer layer of cells, up to 200 µm diam, with central ostiole; wall of 3–6 layers of brown *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Conidiogenous cells** phialidic (mostly monopodial, but a few observed to also be polyphialidic), lining the inner cavity, hyaline, smooth, ampulliform, 5–8 × 3–4 µm, proliferating percurrently (inconspicuous) or with periclinal thickening at apex (also occurring as solitary loci on superficial hyphae surrounding pycnidia). **Conidia** hyaline, smooth, cylindrical, mostly straight, rarely slightly curved, apex subobtuse, base truncate, guttulate, aseptate, (9–)11–13(–18) × 2.5–3(–3.5) µm.

Culture characteristics: Colonies on PDA flat, circular, lacking aerial mycelium, surface fuscous-black, reverse olivaceous-black, after 14 d, 3.5 cm diam; on MEA surface fuscous-black, reverse olivaceous-black, after 14 d, 4.5 cm diam; on OA similar to PDA.

Specimen examined: Spain, Mallorca, El Arenal, on leaves of *Pistacia lentiscus* (Anardiaceae), 25 May 1969, H.A. van der Aa (**holotype** CBS H-21301, culture CBS 471.69).

Notes: *Cylindroseptoria pistaciae* is tentatively placed in *Cylindroseptoria*, as it has pycnidial rather than cupulate conidiomata. However, synapomorphies with *Cylindroseptoria* include phialides with periclinal thickening, and cylindrical, aseptate conidia. Further collections are required to determine if conidiomatal anatomy is more important than conidiogenesis and conidial morphology. For the present, however, the generic circumscription

Fig. 53. Conidia and conidiogenous cells of *Cylindroseptoria pistaciae* (CBS 471.69). Scale bars = 10 µm.

Fig. 52. *Cylindroseptoria ceratoniae* (CBS 477.69). A, B. Conidiomata forming in culture. C, D. Conidiogenous cells giving rise to conidia. E. Conidia. Scale bars: B = 45 µm, all others = 10 µm.

Fig. 54. *Cylindroseptoria pistaciae* (CBS 471.69). A, B. Conidiomata sporulating in culture. C, D. Intercalary chains of chlamydospore-like cells. E, F. Conidiogenous cells. G, H. Conidia. Scale bars = 10 µm.

of *Cylindroseptoria* has been widened to include taxa with pycnidial conidiomata. *Cylindroseptoria pistaciae* could be confused with *Septoria pistaciae*, though conidia of the latter are 20–30 × 1.6 µm, and are 1(–3)-septate (Chitzanidis & Michaelides 2002).

Clade 26: *Pseudoseptoria*

Pseudoseptoria Speg., Ann. Mus. Nac. B. Aires, Ser. 3 13: 388. 1910.

= *Aphanofalx* B. Sutton, Trans. Brit. Mycol. Soc. 86: 21. 1986.

Caulicolous and *foliicolous*, plant pathogenic or saprobic. Conidiomata stromatic, pycnidiod, unilocular, glabrous, black, ostiolate; wall of *textura angularis*, in some cases cells in the upper wall larger and darker than cells in the lower wall. Conidiophores reduced to conidiogenous cells lining the cavity of the conidioma. Conidiogenous cells discrete or integrated, cylindrical or lageniform, colourless, smooth-walled, invested in mucus, with a prominent cylindrical papilla with several percurrent proliferations at the apex; collarette prominent and extending past conidia, or reduced

and inconspicuous. Conidia fusiform, lunate or irregular, curved, unicellular, colourless, smooth-walled with or without an excentric basal appendage, continuous with conidium body, plectronoid to podiform, or with a blunt or spatulate distal end.

Type species: *P. donacicola* Speg., Ann. Mus. Nac. B. Aires, Ser. 3 13: 388. 1910. [= *P. donacis* (Pass.) B. Sutton].

Pseudoseptoria collariana Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804433. Fig. 55.

Etymology: Named after its prominently flared collarettes, forming a sleeve.

On sterile Carex leaves on WA. Conidiomata immersed to erumpent, globose, dark brown, up to 400 µm diam, unilocular, opening via central ostiole; wall of 6–10 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells, or branched at the base with one supporting cell that is dark brown, encased

Fig. 55. *Pseudoseptoria collariana* (CBS 135104). A, B. Colonies sporulating in culture. C–F. Conidiogenous cells with prominent collarettes. G, H. Conidia. Scale bars: A = 400 µm, all others = 10 µm.

Fig. 56. *Pseudoseptoria obscura* (CBS 135103). A, B. Colony sporulating in culture. C. Chlamydospore-like cells developing. D, E. Conidiogenous cells. F–H. Conidia. Scale bars: B = 250 µm, all others = 10 µm.

in a mucilaginous matrix. *Conidiogenous cells* subcylindrical to ampulliform, hyaline, smooth to pale brown, finely verruculose, 18–35 × 3.5–8 µm; apical region with numerous conspicuous percurrent proliferations, with long, prominent collarettes that completely enclose and extend above young, developing conidia, but disintegrating into a mucoid mass with age. *Conidia* fusiform, lunate, curved, aseptate, hyaline, smooth, tapering to an subobtuse apex; base truncate, rarely with a single, unbranched, eccentric basal appendage, 1–2 µm long; conidia (from apex to hilum) (8–)12–14(–15) × (2–)2.5(–3) µm.

Culture characteristics: Colonies on PDA flat, round with feathery margins, lacking aerial mycelium, surface olivaceous-black to rosy-buff for younger tissue, reverse olivaceous-black, to rosy-buff for younger tissue, after 14 d 1.5 cm diam; on MEA surface olivaceous-black to buff for younger tissue, reverse olivaceous-black to brick for younger tissue, after 14 d, 2 cm diam; on OA similar to MEA.

Specimen examined: Iran, Golestan Province, on leaves of Bamboo (Poaceae), 12 May 2009, A. Mirzadi Gohari (**holotype** CBS H-21303, culture ex-type CBS 135103 = CPC 18118).

***Pseudoseptoria obscura* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804434. Fig. 56.

Etymology: Named after the obscure basal appendage that occurs on some conidia.

On sterile Carex leaves on WA. *Conidiomata* immersed to erumpent, globose, dark brown, up to 250 µm diam (smaller than in 18119), unilocular, opening via central ostiole; wall of 3–6 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* subcylindrical to doliform, hyaline, smooth to pale brown, finely verruculose, 6–12 × 2–5 µm; apical region with numerous inconspicuous to conspicuous percurrent proliferations; collarettes absent to prominent. *Conidia* fusiform,

lunate, curved, aseptate, hyaline, smooth, tapering to an subobtuse apex; base truncate, rarely with a single, unbranched, eccentric basal appendage, 1–2 µm long; conidia (from apex to hilum) (8–)12–14(–15) × (2–)2.5(–3) µm.

Culture characteristics: Colonies on PDA flat, undulate with feathery margins, lacking aerial mycelium, surface concentric rings of fuscous-black to pale purplish grey to fuscous-black, reverse concentric rings of greyish-sepia to fawn to fuscous-black, after 14 d, 2 cm diam; on MEA similar to PDA; OA flat, undulate, lacking aerial mycelium, surface fuscous-black to purplish grey for the younger tissue, reverse greyish-sepia to vinaceous-buff for the younger tissue.

Specimen examined: Iran, Golestan Province, on leaves of Bamboo (Poaceae), 12 May 2009, A. Mirzadi Gohari (**holotype** CBS H-21303, culture ex-type CBS 135103 = CPC 18118).

Notes: Species of the genus *Aphanofalx* occur on members of Poaceae, presumably as saprobes. The genus is characterised by having taxa with pycnidial conidiomata, and percurrently proliferating conidiogenous cells, and hyaline, aseptate conidia with a basal, excentric appendage. In contrast, species of *Pseudoseptoria* are known to occur on members of Poaceae as plant pathogens. The genus is also characterised by having taxa with pycnidial conidiomata, and percurrently proliferating conidiogenous cells, and hyaline, aseptate conidia that lack basal appendages. During this study we also investigated three strains identified as *P. donasis* (CBS 291.69, 313.68 and 417.51), the type species of *Pseudoseptoria*. Much to our surprise they formed a monophyletic lineage (results not shown) with the two strains described here (which have basal appendages), suggesting that *Pseudoseptoria* represents an older name for *Aphanofalx*, and that the basal appendage is a species-specific character, as also found in other groups of coelomycetes (Crous et al. 2012b).

Aphanofalx is presently known from two species, *A. mali* (conidia 26–33 × 2–2.5 µm), and *A. irregularis* (conidia 12–28(–31) × (2–)2.5–

3(–3.5) µm (Nag Raj 1993). *Pseudoseptoria collariana* [conidia (24–) 26–28(–30) × (2.5–)3 µm] and *P. obscura* [conidia (8–)12–14(–15) × (2–)2.5(–3) µm] are easily distinguished from these taxa based on their conidial dimensions. The three species of *Pseudoseptoria* treated by Sutton (1980), namely *P. donacis* (conidia 20–23 × 2–2.5 µm), *P. stromaticola* (conidia 16–18.5 × 2 µm) and *P. bromigena* (conidia 20–23 × 2–2.5 µm) can be distinguished from *P. collarata* and *P. obscura* by conidial dimensions, and lacking basal conidial appendages.

Clade 27: *Parastagonospora*

Parastagonospora Quaedvlieg, Verkley & Crous, gen. nov.
Mycobank MB804435.

Etymology: Resembling the genus *Stagonospora*.

Folioicolous, plant pathogenic. Ascocarps immersed, globose, becoming depressed, medium brown to black; wall of 3–6 layers of thick-walled, brown *textura angularis*; ostiole slightly papillate. Ascii clavate, cylindrical or curved, shortly stipitate, 8-spored; ascus wall thick, bitunicate. Ascospores fusoid, subhyaline to pale brown, transversely euseptate (–3), constricted at the septa, penultimate cell swollen. Pseudoparaphyses filiform, hyaline, septate. *Conidiomata* black, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding creamy conidial mass; wall of 2–3 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to subcylindrical, with percurrent proliferation near apex. *Conidia* hyaline, smooth, thin-walled, cylindrical, granular to multi-guttulate, with obtuse apex and truncate base, transversely euseptate.

Type species: *Parastagonospora nodorum* (Berk.) Quaedvlieg, Verkley & Crous.

Notes: The genus *Parastagonospora* is introduced to accommodate several serious cereal pathogens that were formerly accommodated in either *Septoria/Stagonospora*, or *Leptosphaeria/Phaeosphaeria*. As shown previously, *Septoria* is not available for these fungi (Quaedvlieg et al. 2011), and neither is *Leptosphaeria* (de Gruyter et al. 2013). Furthermore, in the present study we also clarify the phylogenetic positions of *Stagonospora* and *Phaeosphaeria*, which cluster apart from this group of cereal pathogens, which are best accommodated in their own genus, *Parastagonospora*.

Parastagonospora is distinguished from *Stagonospora* in that *Stagonospora* has conidiogenous cells that proliferate percurrently, or via phialides with periclinal thickening, and conidia that are subcylindrical to fusoid-ellipsoidal. Sexual morphs known for species of *Parastagonospora* are phaeosphaeria-like, whereas those observed for *Stagonospora* s. str. are didymella-like.

***Parastagonospora avenae* (A.B. Frank) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804436.

Basionym: *Septoria avenae* A.B. Frank, Ber. Dt. Bot. Ges. 13: 64. 1895.

≡ *Stagonospora avenae* (A.B. Frank) Bissett [as 'avena'], Fungi Canadenses, Ottawa 239: 1. 1982

= *Leptosphaeria avenaria* G.F. Weber, Phytopath. 12: 449. 1922.

≡ *Phaeosphaeria avenaria* (G.F. Weber) O.E. Erikss., Ark. Bot., Ser. 2 6: 408. 1967.

= *Pleospora tritici* Garov., Arch. Triennale Lab. Bot. Crittog. 1: 123. 1874.

Specimens examined: Germany, Kiel-Kitzeberg, on *Lolium multiflorum*, 1968, U.G. Schlosser, CBS 290.69, CBS 289.69.

Notes: Although the oldest epithet for this taxon is *Pleospora tritici* (1874), "avenae" has been well established in literature, and accepted by the community. We thus recommend that this epithet be retained for this pathogen. *Parastagonospora avenae* leaf blotch of barley and rye (f.sp. *tritici*), appears distinct from the pathogen on oats (f.sp. *avenaria*) (Cunfer 2000), and further research is required to resolve this issue.

***Parastagonospora caricis* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804437. Figs 57, 58.

Etymology: Named after the host genus from which it was collected, *Carex*.

On sterile *Carex* leaves on WA. *Conidiomata* up to 250 µm diam, black, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding pale pink conidial cirrus; wall of 2–3 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform, 8–15 × 4–6 µm, with percurrent proliferation at apex. *Conidia* hyaline, smooth, thin-walled, scutellosporous, subcylindrical, with subobtuse apex and truncate base, 7–15-septate, (50–)60–70(–75) × (5–)6 µm.

Culture characteristics: Colonies on PDA flat, undulate, with short, white aerial mycelium, surface olivaceous-black in the older parts, vinaceous-buff in the younger mycelium, reverse olivaceous-black in the older parts, brick in the younger mycelium, after 14 d, 4 cm diam; on MEA convex, fimbriate, surface fawn to hazel, reverse fusceous-black to cinnamon, after 14 d, 3 cm diam; on OA similar to MEA.

Specimen examined: Netherlands, Veenendaal, de Blauwe Hel, on leaves of *Carex acutiformis* (Cyperaceae), 25 Jul. 2012, W. Quaedvlieg (**holotype** CBS H-21304, culture ex-type CBS 135671 = S615).

Note: Conidia of *P. caricis* are larger than those of *P. avenae*, which are (1–)3(–7)-septate, 17–46 × 2.5–4.5 µm (Bissett 1982), and narrower than those of *Stagonospora gigaspora*, which are 58–84 × 10–14 µm (Ellis & Ellis 1997).

Fig. 57. Conidia and conidiogenous cells of *Parastagonospora caricis* (CBS H-21304). Scale bars = 10 µm.

Fig. 58. *Parastagonospora caricis* (CBS H-21304). A. Colony sporulating in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Fig. 59. *Parastagonospora nodorum* (CBS H-13909). A, C. Ascomata and conidiomata forming in culture. B, D, F. Asci with ascospores. E, G. Conidia. Scale bars = 10 µm.

***Parastagonospora nodorum* (Berk.) Quaedvlieg, Verkley & Crous, comb. nov.** MycoBank MB804438. Fig. 59.

Basionym: *Depazea nodorum* Berk., Gard. Chron., London: 601. 1845.

- = *Septoria nodorum* (Berk.) Berk., Gard. Chron., London: 601. 1845.
- = *Stagonospora nodorum* (Berk.) E. Castell. & Germano, Annali Fac. Sci. Agr. Univ. Torino 10: 71. 1977. [1975–76]
- = *Leptosphaeria nodorum* E. Müll., Phytopath. J. 19: 409. 1952.
- = *Phaeosphaeria nodorum* (E. Müll.) Hedjar., Sydowia 22: 79. 1969. [1968]

Specimen examined: Denmark, on *Lolium perenne*, Feb. 2002, M.P.S. Câmara, CBS 110109.

Notes: *Parastagonospora nodorum* blotch is an important disease of cereals, having been reported from barley and wheat in most countries where these crops are cultivated (Cunfer 2000). Recent studies have also indicated that *P. nodorum* probably resembles a species complex, awaiting further morphological characterisation (McDonald *et al.* 2013).

***Parastagonospora poae* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804439. Figs 60, 61.

Etymology: Named after the host genus from which it was collected, *Poa*.

On sterile *Carex* leaves on WA. *Conidiomata* up to 250 µm diam, black, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding creamy conidial mass; wall of 2–3 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to subcylindrical, with percurrent proliferation near apex, 6–10 × 3–4(–5) µm. *Conidia* hyaline, smooth, thin-walled, cylindrical, granular, with obtuse apex and truncate base, medianly 1-septate, (20–)25–27(–32) × (2–)2.5(–2.5) µm; ends becoming swollen and guttulate with age.

Culture characteristics: Colonies on PDA flat, circular, with sparse, white aerial mycelium, surface dark-mouse-grey, reverse black,

after 14 d, 8.5 cm diam; on MEA surface hazel, reverse dark-brick to sepia; OA similar to MEA.

Specimens examined: Netherlands, Wageningen, on leaves of *Poa* sp. (Poaceae), 2 Aug. 2012, S. Videira J (**holotype** CBS H-21305, culture ex-type CBS 135089 = S606); Wageningen, on leaves of *Poa* sp., 2 Aug. 2012, S. Videira CBS 135091 = S613.

Note: Conidia of *P. poae* are narrower than those of *P. nodorum*, which are (0–)1–3-septate, 13–28 × 2.8–4.6 µm (Bissett 1982).

Clade 28: *Neostagonospora*

Neostagonospora Quaedvlieg, Verkley & Crous, gen. nov.
Mycobank MB804440.

Etymology: Resembling the genus *Stagonospora*.

Foliicolous. Conidiomata immersed, pycnidial, globose, exuding a pale luteous to creamy conidial mass; wall of 2–3 layers of pale brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliform, tapering at apex with prominent periclinal thickening. Conidia hyaline, smooth, granular, thin-walled, narrowly fusoid-ellipsoidal to subcylindrical, apex subobtusely rounded, base truncate, widest in middle, 1-septate, becoming constricted with age, euseptate, becoming constricted with age.

Type species: *Neostagonospora caricis* Quaedvlieg, Verkley & Crous.

Note: *Neostagonospora* is similar to *Stagonospora* by having pycnidial conidiomata with euseptate, hyaline, fusoid-ellipsoidal to subcylindrical conidia, but distinct in having conidiogenous cells that are phialidic, with prominent periclinal thickening.

Neostagonospora caricis Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804441. Figs 62, 63.

Etymology: Named after the host genus on which it occurs, *Carex*.

On sterile *Carex* leaves on WA. Conidiomata immersed, pycnidial, globose, up to 200 µm diam, exuding a pale luteous to creamy conidial mass; wall of 2–3 layers of pale brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliform, 5–7 × 5–7 µm; tapering at apex with prominent periclinal thickening. Conidia hyaline, smooth, granular, thin-walled, narrowly fusoid-ellipsoidal, apex subobtusely rounded, base truncate, widest in middle, 1-septate, becoming constricted with age, (10–)13–16(–19) × (3–)3.5(–4) µm.

Fig. 60. Conidia and conidiogenous cells of *Parastagonospora poae* (CBS 135091). Scale bars = 10 µm.

Fig. 62. Conidia and conidiogenous cells of *Neostagonospora caricis* (CBS 135092). Scale bars = 10 µm.

Fig. 61. *Parastagonospora poae* (CBS 135091). A, B. Conidiomata forming in culture. C–E. Conidiogenous cells. F, G. Conidia. Scale bars = 10 µm.

Fig. 63. *Neostagonospora caricis* (CBS 135092). A. Conidioma forming in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Culture characteristics: Colonies on PDA flat, undulate, with sparse, powdery white aerial mycelium, surface greyish-sepia to isabelline, reverse olivaceous-grey to pale olivaceous-grey, after 14 d, 8.5 cm diam; on MEA erumpent, circular, with fine white aerial mycelium, surface honey, reverse cinnamon, after 14 d, 6 cm diam; on OA similar to PDA but surface honey, reverse cinnamon.

Specimen examined: Netherlands, Veenendaal, de Blauwe Heil, on leaves of *Carex acutiformis* (Cyperaceae), Aug. 2012, W. Quaedvlieg (**holotype** CBS H-21306, culture ex-type CBS 135092 = S616).

Note: *Neostagonospora caricis* is similar to *Septoria caricis* (conidia 1-septate, 20–35 × 2.5–3 µm; Ellis & Ellis 1997), although its conidia are shorter.

***Neostagonospora elegiae* Quaedvlieg, Verkley & Crous, sp. nov.** MycoBank MB804442. Figs 64, 65.

Etymology: Named after the host genus from which it was collected, *Elegia*.

On *Anthriscus* stem. **Conidiomata** pycnidial, up to 150 µm diam, erumpent, globose, brown, opening by a central ostiole, exuding a crystalline conidial mass; wall consisting of 3–6 layers of pale brown *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Conidiogenous cells** phialidic, lining the inner cavity, hyaline, smooth, ampulliform, 4–7 × 4–6 µm; apex with prominent periclinal thickening. **Conidia** hyaline, smooth, guttulate to granular, scolecosporous, irregularly curved, subcylindrical, apex subobtuse, base truncate (slight taper from apical septum to apex and basal septum to hilum visible in some conidia), (0–)3-septate, (20–)50–65(–70) × (2.5–)3 µm.

Culture characteristics: Colonies spreading, erumpent with moderate aerial mycelium and smooth, even margins; reaching 35 mm diam after 2 wk. On OA pale luteous. On MEA dirty white on surface, luteous in reverse. On PDA dirty white on surface, pale luteous in reverse.

Specimen examined: South Africa, Western Cape Province, Harold Porter Botanical Garden, on leaves of *Elegia cuspidata* (Restionaceae), 30 Nov. 2001, S. Lee (**holotype** CBS H-21307, culture ex-type CBS 135101 = CPC 16977).

Fig. 64. Conidia and conidiogenous cells of *Neostagonospora elegiae* (CBS 135101). Scale bars = 10 µm.

Notes: No septoria-like fungi are presently known from *Elegia* (Lee et al. 2004). *Neostagonospora elegiae* is distinguished from *N. caricis* based on its conidial morphology.

Clade 29: Phaeosphaeriopsis

Phaeosphaeriopsis M.P.S. Câmara, M.E. Palm & A.W. Ramaley, Mycol. Res. 107: 519. 2003.

Saprobic or plant pathogenic. Ascomata solitary or aggregated, immersed, subepidermal to erumpent, pushing up flaps of the epidermis, globose to pyriform, often papillate, solitary or gregarious in a stroma of scleroplectenchyma or dark brown *textura angularis*, often surrounded by septate, brown hyphae extending into the host tissues. Asci 8-spored, bitunicate, cylindrical to broadly fusoid, short stipitate, with visible apical chamber. Ascospores uni- to triseriate, cylindrical, broadly rounded at apex, tapering to narrowly rounded base, 4–5-septate, first septum submedian, often constricted, medium brown, echinulate, punctate or verrucose. Asexual morph coniothyrium-like or phaeostagonospora-like. **Conidiomata** pseudoparenchymatous, sometimes of scleroplectenchyma. **Conidiogenous cells** lining locule, ampulliform, hyaline, proliferating percurrently, resulting in inconspicuous annellations. **Conidia** cylindrical, with bluntly rounded ends, 0–3-septate, yellowish brown, punctate (Câmara et al. 2003, Zhang et al. 2012).

Fig. 65. *Neostagonospora elegiae* (CBS 135101). A. Conidioma forming in culture. B–D. Conidiogenous cells. E. Conidia. Scale bars: A = 150 µm, all others = 10 µm.

Type species: *Phaeosphaeriopsis glaucopunctata* (Grev.) M.P.S. Câmara, M.E. Palm & A.W. Ramaley, Mycol. Res., 107: 519. 2003.

Phaeosphaeriopsis glaucopunctata (Grev.) M.P.S. Câmara, M.E. Palm & A.W. Ramaley, Mycol. Res. 107: 519. 2003. Figs 66, 67.

Basionym: *Cryptosphaeria glaucopunctata* Grev., Fl. Edin.: 362. 1824.

≡ *Paraphaeosphaeria glaucopunctata* (Grev.) Shoemaker & C. E. Babcock, Can. J. Bot. 63: 1286. 1985.

= *Sphaeria risci* Wallr., Fl. Crypt. Germ. 2: 776. 1833.

≡ *Leptosphaeria risci* (Wallr.) Sacc., Syll. Fung. 2: 74. 1883.

≡ *Paraphaeosphaeria risci* (Wallr.) O. E. Eriksson, Ark. Bot., Ser. 2 6: 406. 1967.

Ascomata scattered or aggregated, immersed, globose to subglobose, up to 250 µm diam; peridium up to 25 µm wide, of thick-walled *textura angularis*; hamathecium of dense, wide, cellular pseudoparaphyses, 3–5 µm diam. Ascii 8-spored, bitunicate, cylindrical to broadly fusoid, with a short pedicel and small apical chamber, 50–110 × 10–16 µm. Ascospores uni- to triseriate, cylindrical, medium brown, 4(–5)-septate, without constriction or slightly constricted at the basal septum, the forth cell from the apex usually slightly inflated, the basal cell often longer, 14–28 × (3.5–)5–7.5 µm. Conidiomata pycnidial, immersed, scattered or aggregated, dark brown, subglobose, ostiolate, up to 200 µm diam. Conidiophores reduced to conidiogenous cells. Conidiogenous cells lining the inner cavity, ampulliform, hyaline, smooth, 5–10 × 3–6 µm; proliferating percurrently at apex. Conidia aseptate, smooth to finely verruculose, medium brown, subcylindrical, straight to reniform with obtuse ends, (5–)7–9(–10) × (2.5–)3(–5) µm.

Culture characteristics: On PDA colonies flat, spreading, with sparse aerial mycelium and smooth, lobate, even margins, surface primrose, reverse olivaceous-buff, On OA buff with patches of isabelline due to sporulating conidiomata. On MEA dirty white on surface, isabelline in reverse (centre), cinnamon in outer region.

Specimen examined: Switzerland, Kt. Basel-Stadt, Park Basel, on *Ruscus aculeatus* (Ruscaceae), 25 Sep. 1980, A. Leuchtmann (CBS H-21308, culture CBS 653.86).

Fig. 66. Conidia and conidiogenous cells of *Phaeosphaeriopsis glaucopunctata* (CBS 653.86). Scale bar = 10 µm.

Notes: The genus *Phaeosphaeriopsis* is characterised by having uni- or multiloculate stromata and 4–5-septate ascospores. It presently contains species with coniothyrium-like, and phaeostagonospora-like asexual morphs (e.g. *P. musae*; Arzanlou & Crous 2006). The type species, *Phaeosphaeriopsis glaucopunctata*, is associated with leaf spot and necrosis on *Ruscus aculeatus* (Câmara et al. 2003, Golzar & Wang 2012). The fact that an isolate identified as *Chaetosphaeronema hispidulum* (lectotype of *Chaetosphaeronema*) clusters in this clade is puzzling. The genus *Chaetosphaeronema* is characterised by setose, dark brown pycnidia with thick-walled outer cell layers, producing hyaline, 1-septate conidia (Sutton 1980). Isolate CBS 216.75 proved to be sterile, however, so this matter could unfortunately not be resolved.

Clade 30: *Sclerostagonospora*

Description: See above.

Type species: *S. heraclei* (Sacc.) Höhn., Hedwigia 59: 252. 1917.

Sclerostagonospora phragmiticola Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804443. Fig. 68.

Fig. 67. *Phaeosphaeriopsis glaucopunctata* (CBS 653.86). A. Colony on MEA. B. Colony on OA. C–F. Conidiogenous cells giving rise to conidia. G. Conidia. Scale bars = 10 µm

Fig. 68. *Sclerostagonospora phragmiticola* (CBS 338.86). A. Colony sporulating in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Etymology: Named after the host genus from which it was collected, *Phragmites*.

On sterile Carex leaves on WA. Conidiomata pycnidial, brown, globose, immersed to erumpent, up to 400 µm diam with central ostiole; wall of 6–8 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells lining the inner cavity of conidioma, hyaline to pale olivaceous, smooth, subcylindrical to doliform, 6–15 × 3–4 µm, proliferating several times percurrently at apex. Conidia brown, smooth, subcylindrical, apex obtuse, base truncate, straight to gently curved, (1–)3(–5)-euseptate, older conidia swelling, becoming widest in second or third cell from base, (15–)20–25(–27) × (3–)3.5(–4) µm.

Specimen examined: France, Landes, Seignosse, Étang d'Hardy, on leaves of *Phragmites australis* (Poaceae), 11 June 1986, H.A. van der Aa (holotype CBS H-21309, culture ex-type CBS 338.86).

Notes: *Sclerostagonospora caricicola* fits the concept of *Sclerostagonospora* by having pycnidial conidiomata that give rise to hyaline conidiogenous cells that proliferate percurrently, and subcylindrical, pigmented conidia. Until fresh material of the type species, *S. heraclei* has been re-collected and subjected to DNA analysis, the application of this generic name will remain tentative. Several other species cluster in this clade, suggesting that the sexual morph is phaeosphaeria-like.

Clade 31: *Phaeosphaeria*

Phaeosphaeria I. Miyake, Bot. Mag., Tokyo 23: 93. 1909.

= *Phaeoseptoria* Speg., Revta Mus. La Plata 15: 39. 1908.

Foliicolous. Ascomata immersed, subepidermal, ellipsoidal to globose, glabrous; ostiole central, devoid of periphyses; wall of 2–3 layers of brown *textura angularis*. Pseudoparaphyses transversely septate, guttulate, encased in mucous. Ascii stipitate, clavate to cylindrical, stalked, biseriate. Ascospores brown, narrowly fusiform, straight or slightly curved, transversely septate, smooth to verruculose, enclosed in a mucoid sheath or not. Conidiomata pycnidial, immersed, becoming erumpent, brown, with central ostiole; wall of 2–3 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells hyaline, ampulliform to subcylindrical or doliform; proliferating inconspicuously percurrently near apex. Conidia solitary, pale brown, smooth, guttulate, subcylindrical to narrowly obclavate, apex obtuse, base truncate, straight to curved, transversely euseptate, at times slightly constricted at septa; hilum not darkened nor thickened.

Type species: *P. oryzae* I. Miyake, Bot. Mag. Tokyo, 23(266): 93. 1909.

Notes: *Phaeosphaeria* (1909; based on *P. oryzae*) is congeneric with *Phaeoseptoria* (1908; based on *P. papayaee*). We choose to

use the sexual name *Phaeosphaeria*, as it is well established, and less confused than *Phaeoseptoria*, which has become a confused concept applied to numerous septoria-like taxa with pigmented conidia (see Walker et al. 1992).

***Phaeosphaeria oryzae* I. Miyake, Bot. Mag. Tokyo, 23(266): 93. 1909. Figs 69, 70.**

≡ *Leptosphaerella oryzae* (I. Miyake) Hara, A monograph of rice diseases: 53. 1959.

Fig. 69. Ascii and ascospores of *Phaeosphaeria oryzae* (BPI 744438). Scale bars = 10 µm.

≡ *Leptosphaerulina oryzae* (I. Miyake) Karan, Mycopath. Mycol. Appl. 24: 88. 1964.

= *Phaeoseptoria oryzae* I. Miyake, J. Coll. Agric. Imp. Univ. Tokyo 2(4): 260. 1910.

Ascomata immersed, subepidermal, ellipsoidal to globose, glabrous, up to 150 µm diam, ostiole central, up to 20 µm diam, devoid of periphyses; wall of 2–3 layers of brown *textura angularis*. Pseudoparaphyses 2–3 µm diam, transversely septate, guttulate, encased in mucous. Asci stipitate, cylindrical, 30–55 × 7–9 µm, stalked, biseriate. Ascospores brown, narrowly fusiform, straight or slightly curved, (15–)17–20(–23) × 4(–5) µm, 3-septate, uniformly verruculose, enclosed in a mucoid sheath; after discharge, ascospores become prominently swollen, up to 33 µm long and 8 µm wide.

Specimens examined: Japan, No. 196178, on 2, Prov. Susuya Shizuoka, Sep. 1907, ex Herb. Sydow, ex S., as *Leptosphaeria oryzae* Hori = *Phaeosphaeria oryzae* I. Miyake, slides prepared by O. Eriksson, lectotype (UPS). Korea, on leaf of *Oryza sativa* (Poaceae), intercepted at Port San Francisco, CA, 29 Dec. 1997, coll. L. Hausch, det. M.E. Palm, epitype designated here as BPI 744438, culture ex-epitype CBS 110110 (MBT175330).

Notes: Several detailed accounts of this species are available (Eriksson 1967, Shoemaker & Babcock 1989, Fukuhara 2002). The epitype chosen here closely matches the lectotype in morphology.

***Phaeosphaeria papayae* (Speg.) Quaedvlieg, Verkley & Crous, comb. nov. MycoBank MB804444. Figs 71, 72.**

Basionym: *Phaeoseptoria papayae* Speg., Revta Mus. La Plata: 39. 1908.

Leaf spots associated with infections of *Asperisporium caricae*, amphigenous, pale brown to grey-white, subcircular to angular, 1–5 mm diam, with red-purple margin; conidiomata developing

Fig. 70. *Phaeosphaeria oryzae* (BPI 744438). A. Ascomata on host tissue. B–G. Ascii. H. Ascospores. Scale bars = 10 µm.

and sporulating on leaves when incubated in moist chambers, with white, fluffy mycelium erupting from lesions. *Conidiomata* amphigenous, pycnidial, brown, globose, up to 120 µm diam, with central ostiole, exuding a brown conidial cirrus; wall of 3–4 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner cavity, hyaline, smooth, ampulliform to subcylindrical or doliiiform, 5–12 × 4–6 µm; proliferating inconspicuously percurrently near

apex (conidiogenous cells disintegrating at maturity). *Conidia* solitary, pale brown, smooth, guttulate, subcylindrical to narrowly obclavate, apex obtuse, base truncate, (1–)3(–4)-septate, at times slightly constricted at septa, straight to slightly curved, (15)–26–32(–35) × (2.5)–3 µm; hilum not darkened nor thickened, 2 µm diam. *Ascomata* developed after 4 wk in culture on sterile nettle stems: aggregated in black clusters, globose, up to 150 µm diam, with central ostiole; wall of 2–3 layers of brown *textura angularis*. *Asci* bitunicate, curved to straight, fasciculate, short stipitate with ocular chamber, 40–60 × 8–11 µm. *Pseudoparaphyses* hyaline, smooth, 2–3 µm, septate, constricted at septa, not anastomosing, hypha-like with obtuse ends, distributed among asci. *Ascospores* tri to multiseriate, fusoid, curved to straight, brown, verruculose throughout, somewhat constricted at septa with age, second cell from apex swollen, (18)–24–26(–29) × (3)–4(–5) µm.

Culture characteristics: Colonies with abundant aerial mycelium, covering dish within 2 wk at 24 °C, fast growing, olivaceous-grey on MEA (surface and reverse); margins smooth, even, sterile on MEA, PDA and OA, as well as on SNA with sterile barley leaves.

Specimens examined: Brazil, São Paulo, Botanical Garden, on leaves of *Carica papaya* (Caricaceae), Sep. 1908, IMI 246301, slide ex-holotype; Minas Gerais, Viçosa, UFV campus, on leaves of *Carica papaya*, Mar. 2013, A.C. Alfenas, **epitype** designated here as CBS H-21310, culture ex-epitype CBS 135416 (MBT175331).

Notes: It is interesting to note that Walker *et al.* (1992) also observed *Phaeosphaeria papayae* to co-occur with *Asperisporium*

Fig. 71. Conidia, ascospores and ascus of *Phaeosphaeria papayae* (CBS H-21310). Scale bars = 10 µm.

Fig. 72. *Phaeosphaeria papayae* (CBS H-21310). A. Leaf spot. B. Conidioma with ostiole (arrow). C–E. Conidiogenous cells. F. Conidia. G–K. Asci and ascospores. Scale bars = 10 µm.

caricae on the holotype specimen (noted by Spegazzini as *Cercospora caricae*), suggesting that the co-occurrence of these two pathogens is quite common. The fresh collection obtained in this study enabled us to elucidate the conidiogenesis of the fungus (not observed by Walker *et al.* 1992), and also designate an epitype specimen. Phylogenetically it is closely related to *Phaeosphaeria oryzae*, which has *Phaeocephalothrix oryzae* as asexual morph.

Clade 32: Neosetophoma

Neosetophoma Gruyter, Aveskamp & Verkley, Mycologia 102(5): 1075. 2010.

Foliicolous, plant pathogenic. *Conidiomata* pycnidial, solitary to confluent, on upper surface of agar, globose to irregular, with mycelial outgrowths, or confluent, with papillate ostioles, sometimes developing long necks, honey to olivaceous or olivaceous-black, with up to 10 layers of pseudoparenchymatal cells. *Conidiogenous cells* hyaline, monopodial. *Conidia* slightly yellowish, 0–1(–3)-septate, ellipsoidal to cylindrical, usually attenuate at one end, often guttulate.

Type species: *N. samarorum* Gruyter, Aveskamp & Verkley, Mycologia 102(5): 1075. 2010.

Note: The fact that several strains with a phaeosphaeria-like morphology cluster in this clade, suggests that sexual states do exist for species of *Neosetophoma*.

Clade 33: Paraphoma

Paraphoma Morgan-Jones & J.F. White, Mycota 18: 58. 1983.

Mycelium consisting of branched, septate, subhyaline to pale brown, smooth hyphae. *Conidiomata* pycnidial, solitary to aggregated, superficial to immersed, dark brown, globose to subglobose, papillate, uniloculate, setose; ostiole circular, single; wall of 3–6 layers of brown *textura angularis*. Setae copious, straight to flexuous, smooth to verruculose, thick-walled, septate, pale brown to brown. *Conidiogenous cells* lageniform, monopodial, formed from inner layer of conidiomatal wall, hyaline to subhyaline, discrete. *Conidia* ellipsoid, aseptate, hyaline, smooth, guttulate. *Chlamydospores* if present unicellular.

Fig. 74. *Paraphoma dioscoreae* (CBS 135100). A. Conidioma forming in culture. B–E. Conidiogenous cells. F. Conidia. Scale bars: B = 350 µm, all others = 10 µm.

Type species: *P. radicina* (McAlpine) Morgan-Jones & J.F. White, Mycota 18: 60. 1983.

Paraphoma dioscoreae Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804445. Figs 73, 74.

Etymology: Named after the host genus from which it was collected, *Dioscorea*.

On *Anthriscus* stem. *Conidiomata* pycnidial, separate, immersed becoming erumpent, globose, with papillate neck and central ostiole exuding a crystalline conidial mass; conidiomata up to 350 µm diam, neck up to 150 µm diam, of darker brown cells than body, which is pale brown; wall of 3–6 layers of pale brown *textura angularis*. *Conidiophores* hyaline, smooth, subcylindrical, reduced to conidiogenous cells, 1–5-septate, irregularly branched, 5–20 × 3–5 µm. *Conidiogenous cells* phialidic, hyaline, smooth, ampulliform to subcylindrical (long, elongated neck on *Anthriscus* stem, but not on MEA), 5–15 × 2–3 µm; apex with prominent periclinal thickening, or with several percurrent proliferations (especially on conidiogenous cells with elongated necks). *Conidia* solitary, straight to slightly curved, hyaline, smooth, aseptate, cylindrical with obtuse ends and a guttule at each end, (5–)6(–7) × 2(–2.5) µm.

Fig. 73. Conidia and conidiogenous cells of *Paraphoma dioscoreae* (CBS 135100). Scale bar = 10 µm.

Culture characteristics: Colonies flat, spreading with sparse aerial mycelium and even, smooth margins; after 2 wk reaching 30 mm diam on MEA, 40 mm on PDA and 50 mm on OA. On PDA dark brick, reverse fuscous-black. On OA dark brick with patches of sienna and ochreous. On MEA surface dirty white (due to aerial mycelium), also somewhat sectored, reverse umber.

Specimen examined: South Korea, on leaves of *Dioscorea tokoro* (*Dioscoreaceae*), 24 Oct. 2003, H.D. Shin (holotype CBS H-21311, culture ex-type CPC 11357 = CBS 135100).

Note: *Paraphoma dioscoreae* is phylogenetically distinct from the three other species presently known in the genus (de Gruyter et al. 2010).

Clade 34: *Xenoseptoria*

Xenoseptoria Quaedvlieg, H.D. Shin, Verkley & Crous, gen. nov. MycoBank MB804446.

Etymology: Similar to the genus *Septoria* s. str., but distinct.

Foliicolous, plant pathogenic. Conidiomata separate, pycnidial, immersed becoming erumpent, globose, brown, developing 1–3 papillate necks, exuding a pink to orange conidial mass; wall of 4–8 layers of brown *textura angularis*. Conidiophores hyaline, smooth, reduced to conidiogenous cells or septate, branched below. Conidiogenous cells lining the inner cavity, hyaline, smooth, ampulliform to doliiform or subcylindrical, mono- to polyphialidic, with prominent periclinal thickening, but also with percurrent proliferation. Conidia hyaline, smooth, guttulate, sclecosporous, straight to irregularly curved, cylindrical to obclavate, transversely euseptate, tapering to subobtuse apex, base obtuse.

Type species: *Xenoseptoria neosaccardoi* Quaedvlieg, Verkley & Crous.

Xenoseptoria neosaccardoi Quaedvlieg, H.D. Shin, Verkley & Crous, sp. nov. MycoBank MB804447. Figs 75, 76.

Etymology: Resembling *Septoria saccardoi*, but morphologically distinct.

Leaf spots on the upper leaf surface, scattered, distinct, circular, 2–4 mm diam, initially appearing as reddish brown discolouration, later turning brown to reddish brown without a distinct border line, finally central area becoming greyish brown to dull grey and surrounded by reddish to dark brown margin, reddish pigments may diffuse outward to form a halo; on the lower leaf surface initially showing reddish discolouration, later becoming brown with distinct border line, center greyish brown to grey with indistinct border (Shin & Sameva 2004). On sterile Carex leaves on WA. Conidiomata separate, pycnidial, immersed becoming erumpent, globose, up to 350 µm diam, brown, becoming ostiolate, developing 1–3 papillate necks, exuding a pink to orange conidial mass; wall of 4–8 layers of brown *textura angularis*. Conidiophores hyaline,

Fig. 75. Conidia and conidiogenous cells of *Xenoseptoria neosaccardoi* (CBS 128665). Scale bars = 10 µm.

Fig. 76. *Xenoseptoria neosaccardoi* (CBS 128665). A, B. Pycnidia forming in culture. C–E. Conidiogenous cells. F, G. Conidia. Scale bars: B = 170 µm, all others = 10 µm.

smooth, reduced to conidiogenous cells or 1–2-septate, branched below, 10–20 × 4–6 µm. *Conidiogenous cells* lining the inner cavity, hyaline, smooth, ampulliform to doliiform or subcylindrical, mono- to polyphialidic, with prominent periclinal thickening, but also with percurrent proliferation, 5–15 × 3–5 µm. *Conidia* hyaline, smooth, guttulate, sclecosporous, straight to irregularly curved, cylindrical to obclavate, (1–)3-septate, (23–)33–45(–48) × (2.5–)3(–4) µm, tapering to subobtuse apex, base obtuse, 2–2.5 µm diam.

Culture characteristics: Colonies flat, spreading, with sparse aerial mycelium and lobate, feathery margins, reaching 30 mm after 2 wk. On PDA surface iron-grey, reverse olivaceous-grey; on OA surface olivaceous-grey; on MEA surface folded, bay, reverse umber.

Specimen examined: South Korea, Pyeongchang, on leaves of *Lysimachia vulgaris* var. *davurica* (Primulaceae), 30 May 2007, H.D. Shin (**holotype** CBS H-21312, culture ex-type CBS 128665 = KACC 43962 = SMKC 23666).

Notes: An isolate of *Septoria saccardoi* (CBS 128756) clusters in *Septoria* s. str., thus well apart from this taxon, which was collected in Korea. The Korean collection closely matches that of the original description of *Septoria saccardoi* (on *Lysimachia vulgaris* in Italy), having 3-septate, curved, cylindrical conidia, 38–40 × 3.5 µm, 3-septate (Saccardo & Saccardo 1906). *Xenoseptoria* is however distinct from *Septoria* s. str. in forming pycnidia with multiple papillate necks, and having conidiogenous cells that are mono- or polyphialidic.

Clade 35: *Vrystaatia*

***Vrystaatia* Quaedvlieg, W.J. Swart, Verkley & Crous, gen. nov.** MycoBank MB804449.

Etymology: Named after the Free State Province in South Africa, “Vrystaat” in Afrikaans, where this fungus was collected.

Foliicolous. *Conidiomata* black, globose, pycnidial with central, dark brown ostiolar area, substomatal on host, erumpent in culture;

wall of 6–8 layers of pale brown *textura angularis*; exuding cirrus of orange conidia. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner cavity of conidioma, globose to ampulliform, rarely allantoid, hyaline, smooth; with prominent periclinal thickening, or proliferating several times percurrently near apex, giving rise to macro- and microconidia. *Macroconidia* solitary, hyaline, smooth, guttulate, subcylindrical to narrowly obclavate or acicular, apex obtuse to subobtuse, base truncate to long obconically truncate, conidia widest at or just above basal septum, transversely euseptate. *Microconidia* hyaline, smooth, aseptate, pear-shaped to globose or ellipsoid, apex obtuse, base truncate.

Type species: *Vrystaatia aloeicola* Quaedvlieg, Verkley, W.J. Swart & Crous.

***Vrystaatia aloeicola* Quaedvlieg, Verkley, W.J. Swart & Crous, sp. nov.** MycoBank MB804449. Figs 77, 78.

Etymology: Named after the host genus from which it was collected, Aloe.

Fig. 77. Macro- and microconidia and conidiogenous cells of *Vrystaatia aloeicola* (CBS 135107). Scale bars = 10 µm.

Fig. 78. *Vrystaatia aloeicola* (CBS 135107). A. Conidiomata sporulating on PDA, with characteristic orange conidial cirri. B-D. Conidiogenous cells. E, F. Conidia. Scale bars = 10 µm.

On sterile Carex leaves on WA. Conidiomata black, globose, pycnidial with central, dark brown ostiolar area, substomatal on host, erumpent in culture; wall of 6–8 layers of pale brown *textura angularis*; exuding cirrus of orange conidia. Conidiophores reduced to conidiogenous cells. Conidiogenous cells lining the inner cavity of conidioma, globose to ampulliform, rarely allantoid, hyaline, smooth, 5–12 × 4–6 µm; with prominent periclinal thickening, or proliferating several times percurrently near apex, 2–2.5 µm diam, giving rise to macro- and microconidia. Macroconidia solitary, hyaline, smooth, guttulate, subcylindrical to narrowly obclavate or acicular, apex obtuse to subobtuse, base truncate to long obconically truncate, conidia widest at or just above basal septum, (1–)3-septate, (30–)40–52(–65) × (2.5–)3(–3.5) µm. Microconidia hyaline, smooth, aseptate, pear-shaped to globose or ellipsoid, apex obtuse, base truncate, 4–6 × 3–3.5 µm.

Culture characteristics: On MEA colonies spreading fast, with moderate aerial mycelium and smooth, even margin, reaching 30 mm diam after 2 wk; surface with concentric zones of umber and apricot; reverse umber, produces brown exudates; on PDA round lobate margins, lacking aerial mycelium, reaching 20 mm diam after 2 wk, surface fuscous-black to greyish-sepia for younger mycelium, reverse fuscous-black to greyish-sepia for younger mycelium; on OA round, lobate, lacking aerial mycelium, reaching 30 mm diam after 2 wk, surface vinaceous-grey, reverse greyish sepia.

Specimen examined: South Africa, Orange Free State, Bloemfontein, Free State National Botanical Garden, on dead leaf tips of *Aloe maculata* (Aloaceae), 7 May 2012, P.W. Crous & W.J. Swart (holotype CBS H-21313, culture ex-type CBS 135107 = CPC 20617).

Notes: *Vrystaatia* is distinct from *Septoria* s. str. in that it has phialidic conidiogenous cells that proliferate percurrently or with prominent periclinal thickening, and form macro- as well as microconidia in culture, which is not typical of *Septoria*. *Rhabdospora aloetica* was described from stems of *Aloe* sp. in Portugal, with aseptate conidia, 12–16 × 1.5 µm (Saccardo & Saccardo 1906); it is likely this is an asexual morph of *Diaporthe*. As far as we could establish, no septoria-like fungi have thus far been described from *Aloe*.

Clade 36: *Setophoma*

Setophoma Gruyter, Aveskamp & Verkley, Mycologia 102: 1077. 2010.

Conidiomata pycnidial, solitary to confluent, superficial or submerged in agar, globose to subglobose, setose, with papillate ostioles, honey to olivaceous to olivaceous-black, with 2–7(–11) layers of pseudoparenchymatal cells. Conidiogenous cells hyaline, monoplyalidic. Conidia aseptate, ellipsoidal to subcylindrical to subfusoid, guttulate.

Type species: *S. terrestris* (H.N. Hansen) Gruyter, Aveskamp & Verkley, Mycologia 102: 1077. 2010.

Setophoma chromolaenae Quaedvlieg, Verkley, R.W. Barreto & Crous, sp. nov. MycoBank MB804450. Figs 79, 80.

Fig. 79. Conidia and conidiogenous cells of *Setophoma chromolaenae* (CBS 135105). Scale bar = 10 µm.

Fig. 80. *Setophoma chromolaenae* (CBS 135105). A. Conidiomata forming on OA. B, C, F. Conidiomata with setae. D, E. Conidiogenous cells. G. Conidia. Scale bars: B = 22 µm, C, F = 45 µm, all others = 10 µm.

Etymology: Named after the host genus from which it was collected, *Chromolaena*.

Conidiomata pycnidial, brown, globose, separate, erumpent, up to 90 µm diam; outer surface covered in brown setae, up to 80 µm long, brown, thick-walled, 3–5 µm diam, 1–4-septate, with slight apical taper to obtuse apex; conidial wall of 3–6 layers of brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner cavity, ampulliform, hyaline, smooth, 4–6 × 3–6 µm, with prominent periclinal thickening at apex. *Conidia* hyaline, smooth, subcylindrical, somewhat narrowly ellipsoid when old, with two prominent guttules at ends, (4.5)–5–6 (–7) × (2)–2.5(–3) µm.

Culture characteristics: On MEA spreading, with sparse aerial mycelium, folded surface, margin smooth, lobate; surface umber with patches of apricot and dirty white, reverse ochreous. On PDA surface iron-grey, reverse olivaceous-grey. On OA surface iron-grey, surrounded by orange to apricot diffuse pigment layer in agar; reaching 55 mm diam after 2 wk.

Specimen examined: Brazil, Rio de Janeiro, Fazenda Santa Rosa, Ponte das Laranjeiras, on leaves of *Chromolaena odorata* (Asteraceae), 6 Apr. 2010, R.W. Barreto (**holotype** CBS H-21314, culture ex-type CBS 135105 = CPC 18553).

Note: *Setophoma chromolaenae* is phylogenetically distinct from *S. sacchari* and *S. terrestris*, the two other species presently known from the genus (de Gruyter et al. 2010).

Clade 37: *Coniothyrium* (Coniothyriaceae)

Coniothyrium Corda, Icon. Fung. (Prague) 4: 38. 1840.

Mycelium immersed, consisting of septate, hyaline to brown, branched hyphae. *Conidiomata* pycnidial, separate, globose, pale to dark brown, immersed, unilocular, thin-walled; wall of brown, thick-walled *textura angularis*. *Ostiole* circular, central, papillate or not. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner cavity, phialidic, annellidic, indeterminate, discrete, doliiform to cylindrical, hyaline to pale brown, smooth, several annellations at apex. *Conidia* subcylindrical, spherical, ellipsoid or broadly clavate, brown, thick-walled, 0(–1)euseptate, smooth to verruculose, apex obtuse, base truncate, at times with minute marginal frill (Sutton 1980).

Type species: *C. palmarum* Corda, Icon. Fung. (Prague) 4: 38. 1840.

Coniothyrium sidae Quaedvlieg, Verkley, R.W. Barreto & Crous, sp. nov. MycoBank MB804451. Figs 81, 82.

Etymology: Named after the host genus from which it was collected, *Sida*.

Conidiomata pycnidial, globose, immersed becoming erumpent, up to 200 µm diam; wall consisting of 3–4 layers of subhyaline to pale brown *textura angularis*. *Ostiole* central, papillate, dark brown, up to 30 µm diam, surrounded by a whorl of brown setae, smooth, thick-walled, 4–8-septate, straight to curved, tapering to subobtuse apices, up to 130 µm long, 5–8 µm diam at base. *Conidiogenous cells* hyaline, smooth, lining the inner cavity, ampulliform to

Fig. 81. Conidia and conidiogenous cells of *Coniothyrium sidae* (CBS 135108). Scale bar = 10 µm.

globose, 4–7 × 4–6 µm; apex with prominent periclinal thickening. *Conidia* solitary, hyaline, smooth, aseptate, granular (in Shear's medium, prominently guttulate in lactic acid), fusoid-ellipsoidal, straight to slightly curved, apex obtuse, base truncate to bluntly rounded, (9)–10–12(–13) × (2.5)–3 µm. *Ascomata* developing after several weeks on MEA, separate, pseudothelial, erumpent, uniloculate, papillate, brown, up to 300 µm diam; wall of 4–8 layers of brown *textura angularis*. *Asci* fasciculate, 8-spored, short papillate, hyaline, smooth, subcylindrical, bitunicate, with well-developed apical chamber, 2 µm diam, 55–65 × 8–11 µm. *Ascospores* bi- to triseriate, brown, smooth, guttulate, straight to slightly curved, (3)–5-septate, apical cell obtusely rounded, basal cell somewhat elongated and subobtuse; in ascospores that are 4-septate, the second cell from the apex is markedly swollen, in 5-septate ascospores the third cell from the apex is markedly swollen, (18)–20–24(–26) × (4)–5(–5.5) µm. *Pseudoparaphyses* hyaline, smooth, intermingled among asci, anastomosing, cellular, constricted at septa, up to 80 µm long, 2–4 µm diam.

Culture characteristics: Colonies erumpent, spreading, moderate aerial mycelium even, lobate margins. On MEA surface olivaceous-grey, reverse umber. On OA surface olivaceous-grey with diffuse umber pigment in agar. On PDA surface and reverse olivaceous-grey.

Specimen examined: Brazil, Rio de Janeiro, Nova Friburgo, Riograndina, along roadside on *Sida* sp. (Malvaceae), 24 Feb. 2008, R.W. Barreto (**holotype** CBS H-21315, culture ex-type CPC 19602 = RWB 866 = CBS 135108).

Note: De Gruyter et al. (2013) placed several phoma-like species with a similar morphology in the genus *Coniothyrium*, to which *C. sidae* is allied. Of interest is the paraphaeosphaeria-like sexual morph that developed in culture, which is newly linked here to *Coniothyrium*. The genus *Paraphaeosphaeria* is linked to *Paraconiothyrium* (Verkley et al. 2004).

Clade 38: *Xenobotryosphaeria*

Xenobotryosphaeria Quaedvlieg, Verkley & Crous, gen. nov. MycoBank MB804452.

Etymology: Resembling the genus *Botryosphaeria*, but distinct.

Fig. 82. *Coniothyrium sidae* (CBS 135108). A–E. Conidiomata forming in culture, showing setae. F, G. Conidiogenous cells. H. Conidia. I–K. Asci and ascospores. Scale bars: B, D, E = 100 µm, all others = 10 µm.

Ascomata brown, globose, smooth, ostiolate, superficial on stems; wall of 3–4 layers of brown *textura angularis*. Ascii clavate, hyaline, smooth, short stipitate, fasciculate, bitunicate, thin-walled, apical chamber not visible, 6–8-spored. Ascospores multiseriate, hyaline, smooth and thin-walled, granular, broadly ellipsoid, ends obtuse, aseptate. Pseudoparaphyses not seen.

Type species: *Xenobotryosphaeria calamagrostidis* Quaedvlieg, Verkley & Crous.

Xenobotryosphaeria calamagrostidis Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804453. Figs 83, 84.

Etymology: Named after the host genus from which it was collected, *Calamagrostis*.

Fig. 83. Ascospores and asci of *Xenobotryosphaeria calamagrostidis* (CBS 303.71). Scale bars = 10 µm.

On *Anthriscus* stem. Ascomata brown, globose, smooth, superficial on stems, ostiolate, up to 180 µm diam; wall of 3–4 layers of brown *textura angularis*. Ascii clavate, hyaline, smooth, short stipitate, fasciculate, bitunicate, thin-walled, apical chamber not visible, 6–8-spored, 60–80 × 30–40 µm. Ascospores multiseriate, hyaline, smooth and thin-walled, granular, broadly ellipsoid, ends obtuse, aseptate, (17–)18–20(–24) × (11–)12–13(–14) µm. Pseudoparaphyses not seen.

Culture characteristics: Colonies flat, spreading, with sparse to no aerial mycelium. On PDA surface and reverse dirty white; on MEA concolorous with agar; on OA pale pink on surface.

Specimen examined: Italy, Bergamo Vigolo, on *Calamagrostis* sp. (Poaceae), 20 Jun. 1967, G.A. Hedjaroude (**holotype** CBS H-21316, culture ex-type CBS 303.71).

Notes: Hedjaroude (1968) studied the specimen (ETH 7131; as *Phaeosphaeria silvatica*), but obviously the incorrect fungus was cultivated, as *X. calamagrostidis* is quite distinct from *P. silvatica*, which has cylindrical-fusoid, brown, 6–8-septate ascospores, 18–18 × 4–5 µm. *Xenobotryosphaeria* is reminiscent of genera in the *Botryosphaerales*, but is phylogenetically distinct (Crous *et al.* 2006, Phillips *et al.* 2008, Liu *et al.* 2012). It also resembles species of *Muyocopron* (*Muycopronaceae*), but the latter genus differs in that it has circular, flattened ascomata, as well as prominent pseudoparaphyses, which are absent in *Xenobotryosphaeria*.

Clade 39: *Phoma*

Note: See Aveskamp *et al.* (2010), de Gruyter *et al.* (2009, 2013).

Fig. 84. *Xenobotryosphaeria calamagrostidis* (CBS 303.71). A, C. Ascomata forming in culture. E, G. broken wall with ascospores. B, D, F. Ascospores. H. Ascospores. Scale bars: C = 45 µm, all others = 10 µm.

Clade 40: *Acicuseptoria*

Acicuseptoria Quaedvlieg, Verkley & Crous, gen. nov.
Mycobank MB804454.

Etymology: *Acicu-* from acicular (conidia), and *Septoria* = septoria-like.

Conidiomata pycnidial, erumpent, brown, globose, with central ostiole, exuding a cream conidial mass; wall consisting of 3–6 layers of thin, brown *textura angularis*. **Conidiophores** reduced

to conidiogenous cells. **Conidiogenous cells** hyaline, smooth, ampulliform; proliferating inconspicuously and percurrently at apex, or simply appearing holoblastic. **Conidia** solitary, hyaline, granular, acicular, straight to gently curved, tapering towards apex that is acutely rounded, base truncate, transversely euseptate.

Type species: *Acicuseptoria rumicis* Quaedvlieg, Verkley & Crous.

Acicuseptoria rumicis Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804455. Fig. 85.

Fig. 85. *Acicuseptoria rumicis* (CBS 522.78). A. Conidiomata sporulating in culture. B–E. Conidiogenous cells. F, G. Conidia. Scale bars = 10 µm.

Etymology: Named after the host genus from which it was collected, *Rumex*.

On sterile *Carex* leaves on WA. Conidiomata pycnidial, erumpent, brown, globose, up to 300 µm diam, with central ostiole, exuding a cream conidial mass; wall consisting of 3–6 layers of thin, brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells hyaline, smooth, ampulliform, 7–15 × 5–7 µm; proliferating inconspicuously and percurrently at apex, or simply appearing holoblastic. Conidia solitary, hyaline, granular, acicular, straight to gently curved, tapering towards apex that is acutely rounded, base truncate, 1.5–2 µm diam, up to 8-septate, (32–)40–60(–70) × 2(–2.5) µm.

Culture characteristics: Colonies lobate, flat with little appressed, white aerial mycelium. On MEA surface olivaceous-grey, reverse umber. On OA surface olivaceous-grey. On PDA surface and reverse olivaceous-grey.

Specimen examined: France, Haute Savoie, Mt. Beaudin, 2000 m alt., stem of *Rumex alpinus* (Polygonaceae), Oct. 1978, H.A. van der Aa (**holotype** CBS H-18163, culture ex-type CBS 522.78).

Notes: *Acicuseptoria rumicis* was originally deposited as *Septoria rumicum*, but is distinct from the latter in having acicular, narrower conidia. *Acicuseptoria* is distinct from *Septoria* s. str. in having acicular conidia.

Clade 41: *Stagonospora*

***Stagonospora* (Sacc.) Sacc., Syll. Fung. (Abellini) 3: 445. 1884.**

Description: See above.

Type species: *S. paludosa* (Sacc. & Speg.) Sacc., Syll. Fung. (Abellini) 3: 453. 1884.

Stagonospora duoseptata Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804459. Figs 86, 87.

Etymology: Named after the fact that conidia are 2-septate.

Fig. 86. Conidia and conidiogenous cells of *Stagonospora duoseptata* (CBS 135093). Scale bars = 10 µm.

On sterile *Carex* leaves on WA. Conidiomata dark brown, immersed, subepidermal, pycnidial, globose, up to 400 µm diam, exuding a short, hyaline cirrus of conidia; wall of 3–4 layers of medium brown *textura angularis*. Conidiophores hyaline, smooth, lining inner cavity, 0–1-septate, subcylindrical, 10–20 × 4–5 µm. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, subcylindrical to ampulliform or doliiiform, 6–8 × 3–4 µm; phialidic with several apical percurrent proliferations. Conidia hyaline, smooth, thin-walled, granular, fusoid-ellipsoidal, 2-septate, with septa 4–6 µm inwards from both obtuse conidial ends; conidia widest in middle, (18–)20–23(–25) × (5–)6(–7) µm.

Culture characteristics: Colonies on PDA flattened, circular with lobate edges, and fine grey aerial mycelium, surface mouse-grey, reverse olivaceous-black, after 14 d, 4 cm diam; on MEA after 14 d, 4.5 cm diam; on OA similar to MEA.

Specimen examined: Netherlands, Nijmegen, de Duffelt, on leaves of a *Carex acutiformis* (Cyperaceae), 29 Jul. 2012, W. Quaedvlieg (**holotype** CBS H-21321, culture ex-type CBS 135093 = S618).

Notes: *Stagonospora duoseptata* is distinct from other species occurring on *Carex* in that it has fusoid-ellipsoidal, 2-septate conidia, (18–)20–23(–25) × (5–)6(–7) µm, with septa positioned 4–6 µm inwards from its obtuse conidial ends. *Stagonospora biseptata* (occurring on *Carex lanuginosa*, Wisconsin, USA) has conidia that are larger, (35–)40–50(–55) × (2–)10–11(–13) µm (Greene 1961).

Fig. 87. *Stagonospora duoseptata* (CBS 135093). A. Conidiomata forming in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Stagonospora paludosa (Sacc. & Speg.) Sacc., Syll. Fung. (Abellini) 3: 453. 1884. Figs 88, 89.
Basionym: Hendersonia paludosa Sacc. & Speg., Michelia 1(no. 3): 353. 1878.

On sterile Carex leaves on WA. Conidiomata black, immersed, subepidermal, pycnidial, globose, up to 400 µm diam, exuding a short, hyaline cirrus of conidia; wall of 3–4 layers of medium brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliform, 5–10 × 5–10 µm; tapering at apex with prominent periclinal thickening or 1–2 inconspicuous percurrent proliferations visible at apex. Conidia hyaline, smooth, thin-walled, granular, or each cell with a large central guttule, subcylindrical to fusoid, apex subobtusely to obtusely rounded, base truncate (4–7 µm diam), (6–)7–8-septate (becoming constricted at septa with age), (45–)55–63(–65) × (9–)10–11 µm.

Culture characteristics: Colonies on PDA flat, circular, with grey aerial mycelium, reverse olivaceous-black to buff at the margins, after 14 d, 8.5 cm diam; on MEA umbonate, round, with appressed, grey aerial mycelium, with white patches; OA similar to PDA, but reverse buff with iron-grey patches at the outer region.

Specimens examined: Italy, on *Carex riparia* (Cyperaceae), Feb. 1878, holotype (presumably lost). Netherlands, Utrecht, Veenendaal, de Blauwe Hel, *Carex acutiformis* (Cyperaceae), 23 Jul. 2012, W. Quaedvlieg (**neotype** designated here CBS H-21317, culture ex-type S601 = CBS 135088) (MBT175339).

Notes: For more than a century, *Stagonospora* was confused with *Septoria*. The introduction of molecular techniques around the turn of the century made it possible to definitively establish that *Stagonospora* was not linked to *Septoria*, and that it in fact clusters with other important plant pathogenic genera like *Phoma* and *Leptosphaeria* in the *Pleosporales* (Cunfer & Ueng 1999, Solomon et al. 2006). The type of *Stagonospora* (*S. paludosa*) was re-collected from a *Carex* during this study and phylogenetic analyses showed that this species clustered separately from most other known “*Stagonospora*” spp. (mostly isolated from Poaceae), but together with several other *Stagonospora* species that were also collected from *Carex*. This led to the conclusion that *Stagonospora* s. str. was limited to *Carex*, and that other commercially important stagonospora-like species on Poaceae (e.g. *S. avenae* and *S. nodorum*) in fact belonged to different genera.

Stagonospora perfecta Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804458. Figs 90, 91.

Etymology: Named after the fact that both sexual and asexual morphs of the fungus developed in culture.

On sterile Carex leaves on SNA. Ascomata developing on SNA, solitary, globose, brown, erumpent, up to 300 µm diam, with central ostiole; wall of 3–4 layers of brown *textura angularis*. *Pseudoparaphyses* intermingled among asci, hyaline, smooth, guttulate, multi-septate, constricted at septa, branched, hyphal-like, 4–6 µm diam, filling entire cavity. Asci stipitate, hyaline, smooth, clavate to fusoid-ellipsoidal, bitunicate, with prominent apiculus, 1.5–2.5 µm diam, 8-spored, 45–100 × 12–18 µm. Ascospores hyaline, smooth, 3- to multi-seriate in ascus,

Fig. 88. Conidia and conidiogenous cells of *Stagonospora paludosa* (CBS 135088). Scale bars = 10 µm.

Fig. 90. Conidia, conidiogenous cells and ascus with ascospores of *Stagonospora perfecta* (CBS 135099). Scale bars = 10 µm.

Fig. 89. *Stagonospora paludosa* (CBS 135088). A, B. Conidiomata forming in culture. C, D. Conidiogenous cells. E, F. Conidia. Scale bars: B = 400 µm, all others = 10 µm.

Fig. 91. *Stagonospora perfecta* (CBS 135099). A. Conidiomata forming in culture. B. Ascomata forming in culture. C–F, I, J. Ascii and pseudoparaphyses. G, H. Conidiogenous cells. K. Conidia. Scale bars: B = 300 µm, all others = 10 µm.

fusoid-ellipsoidal with median septum, prominently constricted at septum, tapering towards subobtuse apices, with 1–2 large guttules per cell, thin-walled, widest just above septum in upper cell, (20)–23–25(–27) × (5)–6–7(–8) µm. Conidiomata up to 300 µm diam, brown, immersed, subepidermal, pycnidial, subglobose with central ostiole, exuding crystalline to creamy conidial mass; wall of 2–3 layers of brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliiform or subcylindrical, with several percurrent proliferations near apex, 5–12 × 4–6 µm. Conidia hyaline, smooth, thin-walled, subcylindrical to narrowly fusoid-ellipsoidal, with obtuse apex and bluntly rounded base, 2–3-septate, slightly constricted at septa, with 1–2 large guttules per cell, (19)–25–29(–32) × (6)–7(–8) µm.

Culture characteristics: Colonies on PDA flattened, convex, circular, with white aerial mycelium, surface fuscous-black, reverse iron-grey to black, after 14 d, 8.5 cm diam; on MEA surface fuscous-black, reverse olivaceous-black; on OA surface isabelline, reverse fuscous-black.

Specimen examined: Netherlands, Limburg, Weert, Moerselpeel, on leaves of *Carex acutiformis* (Cyperaceae), Sep. 2012, W. Quaedvlieg (**holotype** CBS H-21320, culture ex-type CBS 135099 = S656).

Notes: *Stagonospora perfecta* is the first species with a confirmed sexual state in the genus *Stagonospora*. Of interest is the fact that it is didymella-like, rather than phaeosphaeria-like in morphology, which also explains its clustering in the *Didymellaceae*. Morphologically *S. perfecta* resembles *S. vitensis* (18–32 × 4–6 µm, 2–3(–4)-septate; Ellis & Ellis 1997), but conidia are wider. *Stagonospora perfecta* is closely related to *S. pseudovitensis*, though in the latter conidia are

slightly longer, more fusoid-ellipsoidal in shape, and lack a sexual morph in culture.

Stagonospora pseudocaricis Quaedvlieg, Verkley, Gardiennet & Crous, sp. nov. MycoBank MB804456. Figs 92, 93.

Etymology: Named after the species that it resembles, *Stagonospora caricis*.

On sterile Carex leaves on WA. Conidiomata black, immersed, subepidermal, pycnidial, globose, up to 400 µm diam, exuding a short, hyaline cirrus of conidia; wall of 3–4 layers of medium brown *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliiform, 5–9 × 5–8 µm; tapering at apex with prominent periclinal thickening or 1–2 inconspicuous percurrent proliferations visible at apex. Conidia hyaline, smooth, thin-walled, granular, or each cell with a large central guttule, subcylindrical to fusoid, apex subobtusely to obtusely rounded, base truncate, (5)–6(–7)-septate, (35)–42–48(–50) × (6)–7–8 µm.

Culture characteristics: Colonies on PDA flat, circular, with appressed, grey aerial mycelium, surface sepia, reverse olivaceous-black to buff, after 14 d, 8.5 cm diam; on MEA umbonate, round, with appressed, grey aerial mycelium with white patches, surface greyish sepia, reverse fuscous-black to olivaceous-black; OA similar to PDA.

Specimens examined: France, Foncegrive, Rive de la Venelle, on *Carex acutiformis* (Cyperaceae), Oct. 2012, A. Gardiennet (**holotype** CBS H-21318, culture ex-type CBS 135132 = S610); *ibid.*, S609 = CBS 135414.

Note: Conidia of *S. pseudocaricis* closely resemble those of *S. caricis* ($25\text{--}45 \times 4\text{--}8 \mu\text{m}$, 5–7-septate; Ellis & Ellis 1997), but are longer.

Stagonospora pseudovitensis Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804457. Figs 94, 95.

Etymology: Named after the species that it resembles, *Stagonospora vitensis*.

On sterile Carex leaves on WA. *Conidiomata* black, immersed, subepidermal, pycnidial, globose with central ostiole, up to $180 \mu\text{m}$ diam; wall of 3–4 layers of pale brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to doliform, $5\text{--}7 \times 4\text{--}5 \mu\text{m}$; tapering at apex with inconspicuous periclinal thickening or percurrent proliferation. *Conidia* hyaline, smooth, thin-walled, granular, subcylindrical with obtuse apex and truncate to bluntly rounded base, $3\text{--}4 \mu\text{m}$ diam, 3-septate, with large central guttule in each cell, $(25\text{--})28\text{--}33(36) \times (6\text{--})7(8) \mu\text{m}$.

Fig. 92. Conidia of *Stagonospora pseudocaricis* (CBS 135132). Scale bar = $10 \mu\text{m}$.

Culture characteristics: Colonies on PDA flat, circular, aerial mycelium consisting of some grey tufts, surface pale mouse-grey, reverse olivaceous-black, after 14 d, 8.5 cm diam; on MEA similar to PDA, but with appressed, white aerial mycelium, and with some grey tufts; OA similar to MEA, but reverse olivaceous-grey.

Specimens examined: Netherlands, Veenendaal, de Blauwe Heil, on leaves of *Carex acutiformis* (Cyperaceae), 23 Jul. 2012, W. Quaedvlieg (holotype CBS H-21319, culture ex-type CBS 135094 = S620); ibid., S602.

Note: Conidia of *S. pseudovitensis* differ from that of *S. vitensis* ($18\text{--}32 \times 4\text{--}6 \mu\text{m}$, 2–3(–4)-septate; Ellis & Ellis 1997), by having consistently 3-septate, wider conidia.

Stagonospora uniseptata Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804460. Figs 96, 97.

Etymology: Named after the fact that conidia are 1-septate.

On sterile Carex leaves on WA. *Conidiomata* up to $150 \mu\text{m}$ diam, black, immersed, subepidermal, pycnidial, globose with central ostiole, exuding yellow conidial masses; wall of 3–4 layers of red-brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* phialidic, hyaline, smooth, aggregated, lining the inner cavity, ampulliform to subcylindrical, $5\text{--}8 \times 3\text{--}4 \mu\text{m}$, with percurrent proliferation at apex. *Conidia* hyaline, smooth, thin-walled, fusoid-ellipsoidal, with obtuse apex and truncate to bluntly rounded base ($2 \mu\text{m}$ diam), medianly 1-septate, prominently constricted at septum, straight to irregularly curved, widest in middle of either apical or basal cell, granular, including yellow-green reflective guttules, $(13\text{--})16\text{--}20(22) \times (5\text{--})5.5(6) \mu\text{m}$.

Fig. 94. Conidia and conidiogenous cells of *Stagonospora pseudovitensis* (CBS 135094). Scale bars = $10 \mu\text{m}$.

Fig. 93. *Stagonospora pseudocaricis* (CBS 135132). A. Conidiomata forming in culture. B, C. Conidia. Scale bars = $10 \mu\text{m}$.

Fig. 95. *Stagonospora pseudovitensis* (CBS 135094). A. Conidiomata forming in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Fig. 96. Conidia and conidiogenous cells of *Stagonospora uniseptata* (CBS 135090). Scale bars = 10 µm.

Fig. 97. *Stagonospora uniseptata* (CBS 135090). A. Conidiomata sporulating in culture. B. Conidiogenous cells. C. Conidia. Scale bars = 10 µm.

Culture characteristics: Colonies on PDA appressed, circular, with short, greyish-white aerial mycelium, surface fusous-black, reverse olivaceous-black to hazel, after 14 d, 8.5 cm diam; on MEA surface hazel, reverse cinnamon; on OA with patches of white aerial mycelium, surface isabelline, reverse olivaceous to fuscous-black.

Specimens examined: **Netherlands**, Nijmegen, de Duffelt, on leaves of a *Carex acutiformis* (Cyperaceae), 29 Jul. 2012, W. Quaedvlieg, (holotype CBS H-21322, culture ex-type CBS 135090 = S611); *ibid.*, S607, S608 = CPC 22151 and CPC 22150.

Notes: Of the *Stagonospora* and *Septoria* species occurring on *Carex*, *Stagonospora uniseptata* is most similar to *Septoria caricis* (conidia 20–35 × 2.5–3 µm, 1-septate; Ellis & Ellis 1997), but distinct in that conidia are shorter and wider.

Clade 42: *Corynespora*

Corynespora Güssow, Z. PflKrankh. PflPath. PflSchutz 16: 10. 1906.

Mycelium immersed or superficial. **Stroma** present in some species. **Setae** and **hyphopodia** absent. **Conidiophores** macronematous, mononematous, straight or flexuous, unbranched, brown or olivaceous brown, smooth. **Conidiogenous cells** monotretic, integrated, terminal, percurrent, cylindrical or doliform. **Conidia** solitary or catenate, dry, acrogenous, simple, obclavate, rarely cylindrical, subhyaline, pale to dark brown or olivaceous brown or straw-coloured, euseptate or distoseptate, smooth, rarely verruculose (Ellis 1971).

Type species: *C. mazei* Güssow, Conspl. Regni Veget. (Leipzig) 16: 13. 1906. [= *C. cassiicola* (Berk. & M.A. Curtis) C.T. Wei, Mycol. Pap. 34: 5. 1950.]

Corynespora leucadendri Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804461. Figs 98, 99.

Etymology: Named after the host genus from which it was collected, *Leucadendron*.

On MEA and PDA after 2 wk. **Mycelium** consisting of creeping, branched, septate, hyaline, smooth, 3–4(–5) µm diam hyphae that become brown close to conidiophores; stroma lacking. **Conidiophores** subcylindrical, erect, medium brown, 100–300 µm tall, 4–6(–7) µm diam, thick-walled, transversely multiseptate, with several swollen nodes of conidiophore rejuvenation (up to 12 µm diam). **Conidiogenous cells** terminal, cylindrical, medium brown, smooth, ends swollen or not, central locus somewhat darkened or inconspicuous, 15–40 × 5–6(–7) µm. **Conidia** medium brown, obclavate to subcylindrical, straight to slightly curved, thick-walled, (3–)4–6(–10)-distoseptate, basal locus thickened, darkened, protruding, 2–3 µm diam, (35–)70–110(–170) × (6–)7–8(–11) µm.

Fig. 98. Conidia and conidiogenous loci of *Corynespora leucadendri* (CBS 135133). Scale bar = 10 µm.

Culture characteristics: Colonies erumpent, spreading with moderate aerial mycelium and smooth, even margin; reaching 25 mm diam after 2 wk. On MEA surface dirty white, reverse cinnamon. On PDA surface dirty white, reverse buff to rosy buff with diffuse rosy buff pigment. On OA surface dirty white with diffuse rosy buff pigment in agar.

Specimen examined: South Africa, Western Cape Province, Helderberg Nature Reserve, from the leaves of *Leucadendron* sp. (Proteaceae), 14 Aug. 2000, S. Lee (holotype CBS H-21323, culture ex-type CBS 135133 = CPC 19345).

Notes: This species was not treated by Marincowitz et al. (2008), and presently no species of *Corynespora* are known from *Leucadendron*. Furthermore, based on conidial morphology, none of the species treated by Ellis (1971, 1976) resemble *C. leucadendri*, nor is it similar to any *Corynespora* sequence presently deposited in GenBank. For these reasons we thus introduce *C. leucadendri* as a new taxon.

Clade 43: *Setoseptoria*

Setoseptoria Quaedvlieg, Verkley & Crous, gen. nov. MycoBank MB804462.

Etymology: Named after its conidiomata which are septoria-like, but setose.

Conidiomata pycnidial, brown, immersed, globose with central ostiole, somewhat papillate, apical erumpent part at times with brown, verruculose to warty setae; wall of 6–8 layers of brown *textura angularis*; inner layer of 6–10 layers of hyaline *textura angularis*. **Conidiophores** lining the inner cavity, reduced to conidiogenous cells, or with one supporting cell. **Conidiogenous cells** hyaline, smooth, subcylindrical to doliform; apical region with several inconspicuous percurrent proliferations, or with pericinal thickening; collarette inconspicuous, or prominent, flared. **Conidia** hyaline, smooth, becoming somewhat olivaceous and verruculose in older cultures, subcylindrical, tapering in apical part to obtuse or subobtuse apex, base truncate, transversely euseptate, straight to somewhat curved, mostly with one large central guttule per cell, older conidia becoming constricted at septa, disarticulating into phragmospores.

Type species: *Setoseptoria phragmites* Quaedvlieg, Verkley & Crous.

Fig. 99. *Corynespora leucadendri* (CBS 135133). A–C. Conidiogenous cells giving rise to conidia. D. Conidia. Scale bars = 10 µm.

Fig. 100. *Setoseptoria phragmitis* (CBS 114802). Conidioma sporulating in culture. B. Setae. C, D. Conidiogenous cells. E. Conidia. Scale bars = 10 µm.

Setoseptoria phragmitis Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804463. Fig. 100.

Etymology: Named after the host genus from which it was collected, *Phragmites*.

On sterile Carex leaves on WA. Conidiomata pycnidial, brown, immersed, globose with central ostiole, up to 30 µm diam, somewhat papillate, up to 200 µm diam, apical erumpent part at times with brown, verruculose to warty setae; wall of 6–8 layers of brown *textura angularis*; inner layer of 6–10 layers of hyaline *textura angularis*. Conidiophores lining the inner cavity, reduced to conidiogenous cells, or with one supporting cell. Conidiogenous cells hyaline, smooth, subcylindrical to doliiiform, 7–12 × 3–4 µm; apical region with several inconspicuous percurrent proliferations, or with periclinal thickening; collarette inconspicuous, or prominent, flared. Conidia hyaline, smooth, becoming somewhat olivaceous and verruculose in older cultures, subcylindrical, (1–)3-septate, (19–)25–35(–38) × (3.5–)4 µm, tapering in apical part to obtuse or subobtuse apex, base truncate, 1.5–2.5 µm diam, straight to somewhat curved, mostly with one large central guttule per cell, older conidia becoming constricted at septa, disarticulating into phragmospores.

Culture characteristics: Colonies on PDA umbonate, round, fluffy grey white aerial mycelium on the younger parts with longer grey blackish tufts on the older parts, surface olivaceous-black to buff at the younger mycelium, reverse olivaceous-black at the older parts to buff at the younger mycelium, after 14 days 6 cm diam; on MEA similar to PDA but after 14 d, 7 cm diam; on OA similar to PDA.

Specimens examined: Hong Kong, Mai Po Mangrove, from the leaves of *Phragmites australis* (Poaceae), 12 Mar. 1998, K.D. Hyde (**holotype** CBS H-21324, culture ex-type CBS 114802 = HKUCC 2689); *ibid.*, 3 Feb. 2000, K.D. Hyde (CBS 114966 = HKUCC 6029).

Notes: *Setoseptoria* needs to be compared to *Dearnessia* and *Trichoseptoria* (see above). The genus *Trichoseptoria* is poorly known, and details about its conidiogenesis is lacking, and thus it cannot be compared until it has been recollected. *Setoseptoria* is distinct from *Dearnessia* in that it has conidiogenous cells with prominent percurrent proliferation, and conidia that tend to become olivaceous and verruculose in older cultures, and disarticulate into phragmospores. Several *Septoria* species have been described from *Phragmites*, including *S. phragmitis* (conidia 20–30 × 1.5–2

µm), *S. arundinacea* (conidia 6–7-septate, 60–70 × 5–6 µm), *S. curva* (conidia 14–20 × 3.5–4.5 µm), and *S. graminum* (conidia multiseptate, 55–75 × 1–1.3 µm), all of which appear to differ from *Setoseptoria phragmitis* based on its conidial morphology.

Clade 44: *Septorioides*

Septorioides Quaedvlieg, Verkley & Crous, gen. nov. MycoBank MB804464.

Etymology: Resembling the genus *Septoria*.

Foliicolous. Conidiomata black, unilocular, globose, flattened, opening by means of irregular rupture; wall consisting of 6–10 layers of dark brown *textura irregularis* to *angularis*, exuding a crystal conidial mass. Paraphyses intermingled among conidiophores, hyaline, cylindrical, branched at base, septate with obtuse ends. Microconidia hyaline, smooth, cylindrical, mostly straight, apex obtuse, base truncate. Conidiophores reduced to conidiogenous cells or with a supporting cell. Conidiogenous cells lining the inner cavity in basal layer, hyaline, smooth, subcylindrical to ampulliform, giving rise to macro- and microconidia. Spermatia formed in conidiomata, cylindrical, hyaline, smooth, straight to curved. Macroconidia hyaline, smooth, guttulate, subcylindrical, straight to irregularly curved, tapering in apical cell to subobtuse apex, base truncate, transversely euseptate.

Type species: *Septorioides pini-thunbergii* (S. Kaneko) Quaedvlieg, Verkley & Crous.

Septorioides pini-thunbergii (S. Kaneko) Quaedvlieg, Verkley & Crous, comb. nov. MycoBank MB804465. Fig. 101.

Basionym: *Septoria pini-thunbergii* S. Kaneko, Trans. Mycol. Soc. Japan 30(4): 463. 1989.

Associated with needle blight, or isolated as endophyte. On PDA. Conidiomata black, unilocular, globose, flattened, up to 400 µm diam, opening by means of irregular rupture; wall consisting of 6–10 layers of dark brown *textura irregularis* to *angularis*, exuding a crystal conidial mass. Paraphyses intermingled among conidiophores, hyaline, cylindrical, branched at base, septate with obtuse ends, 2–2.5 µm diam, up to 80 µm long. Microconidia hyaline, smooth,

Fig. 101. *Septorioides pini-thunbergii* (CBS 473.91). A. Colony sporulating on PDA. B. Spermatia. C–E. Conidiogenous cells. F. Conidia. Scale bars = 10 µm.

cylindrical, mostly straight, apex obtuse, base truncate, 5–15 × 2–2.5 µm. Conidiophores reduced to conidiogenous cells or with a supporting cell. Conidiogenous cells lining the inner cavity in basal layer, hyaline, smooth, subcylindrical to ampulliform, 10–15 × 4–6 µm, giving rise to macro- and microconidia. Spermatia formed in conidiomata, cylindrical, hyaline, smooth, straight to curved, 3–7 × 2 µm. Macroconidia hyaline, smooth, guttulate, subcylindrical, straight to irregularly curved, tapering in apical cell to subobtuse apex, base truncate, (60–)70–80(–110) × 3.5(–4) µm, (1–)3–6(–10)-septate.

Specimen examined: Japan, Akita Prefecture, Tenno-cho, on needles of *Pinus thunbergii* (Pinaceae), Aug. 1984, S. Kaneko & Y. Zinno, culture ex-type of *Septoria pini-thunbergii* (CBS 473.91).

Note: *Septorioides* is distinguished from *Septoria* by having conidiomata that open by means of an irregular split (acervular), and having paraphyses intermingled among its conidiophores. *Septorioides pini-thunbergii* was originally described from blighted needles of *Pinus thunbergii* in Japan (Kaneko et al. 1989). It was also recently isolated as endophyte from needles of *P. densiflora* in Korea (Yoo & Eom 2012).

Clade 45: *Phlyctema*

Phlyctema Desm., Ann. Sci. Nat., Sér. 3, 8: 16. 1847.

= *Allantozythia* Höhn., Mykol. Unters. 3: 322. 1923.

Mycelium immersed, branched, septate, hyaline. **Conidiomata** eustromatic, immersed, erumpent, sporodochial, separate, yellowish brown, pulvinate, circular, unilocular but convoluted, thick-walled; wall of *textura angularis*, darker brown and thicker-walled at base than at the sides. **Ostiole** absent, dehiscence by irregular rupture. **Conidiophores** hyaline, septate, branched irregularly, cylindrical to filiform, formed from the wall lining the conidiomata. **Conidiogenous cells** enteroblastic, phialidic, integrated or discrete, determinate, hyaline, with minute collarette and periclinal thickening. **Conidia** hyaline, aseptate, fusiform, eguttulate, straight to slightly curved or irregular (Sutton 1980).

Type species: *P. vagabunda* Desm., Ann. Sci. Nat., Bot., Sér. 3, 8: 16. 1847.

Notes: *Phlyctema* is characterised by having eustromatic, convoluted, pulvinate to sporodochial conidiomata, branched,

hyaline conidiophores, and phialidic conidiogenous cells that give rise to hyaline, aseptate, fusiform, straight to curved conidia. The genus has more than 80 names, and is in need of revision. The type species is linked to a sexual morph known as *Neofabraea alba* (Verkley 1999).

Phlyctema vincetoxicici Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804466. Figs 102, 103.

Etymology: Named after the host genus from which it was collected, *Vincetoxicum*.

Conidiomata immersed, separate, eustromatic, unilocular, convoluted, opening by irregular rupture, becoming acervular to sporodochial, up to 450 µm diam; wall of 3–6 layers of brown *textura angularis*; outer surface covered in brown, warty hyphae. **Conidiophores** hyaline, smooth, subcylindrical, lining the inner layer, branched, 1–4-septate, 15–50 × 4–5 µm. **Conidiogenous cells** phialidic, hyaline, smooth, subcylindrical to cymbiform or doliform, with apical periclinal thickening and minute, non-flaring collarette, 7–18 × 3.5–5 µm. **Conidia** hyaline, smooth, guttulate, aseptate, fusiform, curved, tapering to subobtuse apex and truncate base, (27–)33–37(–40) × 3(–3.5) µm.

Fig. 102. Conidia and conidiogenous cells of *Phlyctema vincetoxicici* (CBS 123727). Scale bar = 10 µm.

Fig. 103. *Phlyctema vincetoxicci* (CBS 123727). A. Colonies forming on OA. B, C. Conidiogenous cells. D. Conidia. Scale bars = 10 µm.

Culture characteristics: Colonies on PDA flat, circular, with sparse, white aerial mycelium, surface dark-brick, reverse greyish sepia, after 14 d, 7 cm diam; on MEA undulate, lacking aerial mycelium, after 14 d, 6 cm diam; on OA flat, circular, lacking aerial mycelium, after 14 d, 8.5 cm diam.

Specimen examined: Czech Republic, Moravia, Podyji National Park, Masovice, Klinka area, on leaves of *Vincetoxicum officinale* (Asclepiadaceae), 17 Sep. 2008, G. Verkley (holotype CBS H-21325, culture ex-type CBS 123727 = V6015.2).

Notes: No species of *Phlyctema* has thus far been described on *Vincetoxicum*. *Septoria vincetoxicci* (conidia 30–50 × 1–1.5 µm; Saccardo 1884) has somewhat longer, narrower conidia. *Phlyctema vincetoxicci* was found sporulating in leaf spots showing numerous hypophylloous teleospore sori of the rust fungus *Cronartium flaccidum* (identified by H.A. van der Aa).

Clade 46: *Kirstenboschia*

Kirstenboschia Quaedvlieg, Verkley & Crous, gen. nov.
MycoBank MB804467.

Etymology: Kirstenbosch National Botanical Garden is one of the most acclaimed botanical gardens of the world, set against the foot of Cape Town's Table Mountain. With more than 7000 plant species, it has also proven to be a source of numerous undescribed fungal species. Kirstenbosch was established in 1913, and to celebrate its centenary (2013), the fungal genus *Kirstenboschia* is named after this beautiful garden.

Foliicolous. Conidiomata erumpent, sporodochial, separate, with slightly raised outer margin of 3–10 layers of *textura intricata*. Conidiophores lining the inner cavity, hyaline, smooth, septate, subcylindrical, branched below and above. Conidiogenous cells terminal and lateral, hyaline, smooth, ampulliform to subcylindrical, proliferating sympodially, apical loci truncate, at times appearing subdenticulate, 1 µm diam. Conidia solitary, hyaline, sclecosporous, smooth, granular, thin-walled, acicular to narrowly obclavate with subobtuse apex and truncate to long obconically truncate base, 3-septate, irregularly curved.

Type species: *K. diospyri* Quaedvlieg, Verkley & Crous.

Kirstenboschia diospyri Quaedvlieg, Verkley & Crous, sp. nov. MycoBank MB804468. Figs 104, 105.

Etymology: Named after the host genus from which it was collected, *Diospyros*.

Conidiomata erumpent, sporodochial, up to 300 µm diam, separate, appearing creamy to pale yellow when sporulating on SNA with barley leaves, with slightly raised outer margin of 3–10 layers of *textura intricata*. Conidiophores lining the inner cavity, hyaline, smooth, 0–4-septate, subcylindrical, branched below and above, 5–15 × 2–4 µm. Conidiogenous cells 5–10 × 2–3 µm, terminal and lateral, hyaline, smooth, ampulliform to subcylindrical, proliferating sympodially, apical loci truncate, at times appearing subdenticulate, 1 µm diam. Conidia solitary, hyaline, sclecosporous, smooth, granular, thin-walled, acicular to narrowly obclavate with subobtuse apex and truncate to long obconically truncate base, 3-septate, irregularly curved, (40–)60–70(–75) × (1.5–)2 µm.

Culture characteristics: Colonies on PDA erumpent, with moderate aerial mycelium, and smooth, lobate margin; surface and reverse dirty white. On OA dirty white with diffuse brown pigment in agar. On MEA surface folded, irregular, strongly erumpent, dirty white, reverse sienna.

Fig. 104. Conidia and conidiogenous cells of *Kirstenboschia diospyri* (CBS 134911). Scale bars = 10 µm.

Fig. 105. *Kirstenboschia diospyri* (CBS 134911). A. Conidiomata forming in culture. B, C. Conidiogenous cells. D. Conidia. Scale bars: A = 300 µm, all others = 10 µm.

Specimen examined: South Africa, Western Cape Province, Kirstenbosch Botanical Garden, on leaves of *Diospyros whyteana* (Ebenaceae), 9 Aug. 2011, P.W. Crous (**holotype** CBS H-21326, culture ex-type CBS 134911 = CPC 19869).

Note: *Kirstenboschia* is distinguished from *Septoria* s. str. and allied genera based on its distinctive, sporodochial conidiomata, and conidiogenous cells that proliferate sympodially, but at times are subdenticulate.

Clade 47: *Phlog cylindrium*

Phlog cylindrium Crous, Summerb. & Summerell, Fungal Diversity 23: 340. 2006.

*Foliicolous. Conidiomata synnematal to sporodochial, pale brown. Macroconidiophores arising from a brown stroma of 3–6 layers of *textura angularis*, giving rise to subcylindrical, hyaline (dark brown at the base), smooth, frequently branched conidiophores, 0–2(–6)-septate. Macroconidiogenous cells* hyaline, smooth, subcylindrical, proliferating sympodially and percurrently near apex. *Macroconidia* hyaline, smooth, subcylindrical, transversely septate, apex obtusely rounded, base truncate, slightly curved. *Microconidia* formed in acervular conidiomata together with macroconidia. *Microconidiophores* intermingled among macroconidiophores, hyaline, smooth, subcylindrical, branched, 1–4-septate. *Microconidiogenous cells* terminal and lateral, hyaline, smooth, ampulliform, phialidic, 5–16 × 2–2.5 µm, solitary or in penicillate clusters of up to 3. *Microconidia* hyaline, smooth, hamate, curved, apex subobtuse, base truncate, widest in upper third, aseptate, (16–)17–20(–24) 1.5(–2) µm.

subcylindrical, 10–15 × 2–4 µm, proliferating sympodially and percurrently near apex. *Macroconidia* hyaline, smooth, subcylindrical, 1(–3)-septate, apex obtusely rounded, base truncate, slightly curved, (27–)40–50(–55) × 2–2.5(–3) µm. *Microconidia* formed in acervular conidiomata together with macroconidia. *Microconidiophores* intermingled among macroconidiophores, hyaline, smooth, subcylindrical, branched, 1–4-septate, 20–40 × 2–2.5 µm. *Microconidiogenous cells* terminal and lateral, hyaline, smooth, ampulliform, phialidic, 5–16 × 2–2.5 µm, solitary or in penicillate clusters of up to 3. *Microconidia* hyaline, smooth, hamate, curved, apex subobtuse, base truncate, widest in upper third, aseptate, (16–)17–20(–24) 1.5(–2) µm.

Specimens examined: Australia, Victoria, Otway Ranges, (near Gellibrand), latitude: -38.568412, longitude: 143.539586, elevation: 175 m, on leaves of *Eucalyptus globulus* (Myrtaceae), Sep. 2005, I. Smith, **holotype** CBS H-19771, cultures ex-type CPC 12429 = CBS 120221; New South Wales, on leaves of *E. nitens*, 22 Nov. 1996, P.W. Crous (CBS 111689 = CPC 1547 = STE-U 1547).

Notes: The present strain represents the second collection of this fungus. Isolates from this collection formed a microconidial state not observed in the type (Crous et al. 2007c), and novel for species of *Phlog cylindrium*.

Fig. 106. Macro- and microconidia and conidiogenous cells of *Phlog cylindrium eucalyptorum* (CBS 111689). Scale bars = 10 µm.

Phlog cylindrium eucalyptorum Crous, Fungal Planet 20. 2007. Figs 106, 107.

On OA. *Conidiomata* synnematal to sporodochial, pale brown up to 300 µm diam. *Macroconidiophores* arising from a brown stroma of 3–6 layers of *textura angularis*, giving rise to subcylindrical, hyaline (dark brown at the base), smooth, frequently branched conidiophores, 0–2(–6)-septate, 15–25(–45) × 3–4 µm. *Macroconidiogenous cells* hyaline, smooth,

Fig. 107. *Phlogiellidium eucalyptorum* (CBS 111689). A. Colony on OA. B, E. Microcyclic conidiation with macro- and macroconidia. C. Macroconidiogenous cells. D. Microconidia. F. Macroconidia. Scale bars = 10 µm.

DISCUSSION

The main question considered in the present study was: what is *Septoria*? To address this we included 370 isolates representing 170 species, sampled from six continents. Furthermore, we also generated several phylogenetic datasets based on partial sequences of the ITS, LSU, Btub, RPB2 and EF-1 α loci. In the final analysis, it was clear that *Septoria* is a well-defined genus and phylogenetic clade, with pycnidial, ostiolate conidiomata, conidiophores reduced to conidiogenous cells that proliferate sympodially, and hyaline, filiform conidia with transverse eusepta, fitting the original concept of Sutton (1980). However, when host material has been incubated for a while, several pycnidial species tend to form acervuli (also not clearly defined when studied in culture on normal agar media), and conidiogenous cells could have a combination of sympodial and percurrent proliferation (as observed in *Pseudocercospora*; Crous *et al.* 2013).

The present study, including that of Verkley *et al.* (2013) defined an additional 15 genera that were formerly treated as “septoria” in the widest sense. Although it has recently been shown that *Phoma* is a generic complex representing many morphologic and phylogenetic genera (Aveskamp *et al.* 2010, de Gruyter *et al.* 2010, 2013), this was not expected to also be the case for *Septoria*. Furthermore, many of the septoria-like genera discussed earlier in this paper are presently still not known from sequence, and thus their phylogeny remains to be resolved, meaning that they could add further entities to the list of acknowledged septoria-like genera.

Although *Septoria* s. str. is a genus in the Mycosphaerellaceae (*Capnodiales*), several of the septoria-like genera clustered outside this family. Species of *Septoria* are morphologically conserved, and in the past many taxa were identified based on host, which has been shown to be unreliable (see Verkley *et al.* 2013), as several taxa have wide host ranges. Another complication revealed in the present study is that many septoria-like genera cluster in different phylogenetic clades, but have still retained the *Septoria* morphological characters, which means that as in *Phoma*, future

identifications in this complex will also have to rely on DNA sequence data to support morphological conclusions.

The genus *Stagonospora* has always been separated from *Septoria* on the basis that *Septoria* has conidiogenous cells with sympodial proliferation, whereas in *Stagonospora* they proliferate percurrently. As shown in the present study, however, conidiogenesis is far too broad a feature to define all genera that express these modes of proliferation in their conidiogenous cells. *Stagonospora*, which is based on *S. paludosa*, was epitypified in this study, and shown to cluster apart from *Septoria* s. str. Another major surprise lies in the fact that *Septoria nodorum* blotch, caused by “*Stagonospora*” *nodorum*, clusters in a distinct genus, unrelated to *Stagonospora* s. str., and also separate from *Phaeosphaeria* s. str. A repercussion from these findings is the fact that the common cereal pathogens, which are neither *Stagonospora*, *Septoria*, *Phaeosphaeria* or *Leptosphaeria* (see de Gruyter *et al.* 2013), now have to be accommodated in a new genus, *Parastagonospora*. Furthermore, it appears that *Stagonospora* s. str. occurs on Poaceae, but has thus far only been confirmed from *Carex*, though further sampling will undoubtedly extend the host range of this genus. *Parastagonospora* is thus a novel, distinct stagonospora-like genus, which has sexual morphs that are phaeosphaeria-like in morphology, thus quite unlike those of *Stagonospora* s. str., which are more didymella-like in morphology.

The genus *Phaeosphaeria* is based on *P. oryzae* (asexual morph *Phaeoseptoria oryzae*), for which we could designate an epitype in this study. Furthermore, we also recollected the type species of *Phaeoseptoria*, *P. papayae*, for which we also designated an epitype. As expected, *Phaeoseptoria* clusters with *Phaeosphaeria*, for which we choose the name of the sexual morph, *Phaeosphaeria*, on the basis that it is clearly resolved, and well established in literature. In contrast, *Phaeoseptoria* has in recent years become a muddled concept harbouring unrelated coelomycetes with pigmented conidia.

Obtaining a culture of *Cytostagonospora martiniana* clarified the phylogenetic position of the genus as distinct from *Septoria*, resolving the difference of opinion between von Arx (1983), who regarded it as synonym of *Septoria*, versus Sutton (1980), who

retained it as separate genus. Of interest is the unique mode of conidiogenesis, ranging from holoblastic sympodial to polyphialides with periclinal thickening to percurrent proliferation. It should be noted, however, that although this is a distinct genus, *C. mariniana* is not the type of *Cystostagonospora*, and *C. photiniicola* (occurring on *Photinia serrulata*, Austria) will have to be re-collected to confirm that these two fungi are congeneric.

The genus *Phloeospora* (based on *P. ulmi*) has for long been assumed to be a synonym of *Septoria* based on morphology. It is thus good to finally see it resolved as separate phylogenetic lineage, which is also supported morphologically based on its acervular conidiomata and conidiogenous cells with prominent percurrent proliferation. In spite of resolving 21 genera, several lineages remain unresolved, and are simply treated as “*Septoria*-like” awaiting the recollection of additional material.

It is surprising that so many of the cereal pathogens actually have a confused taxonomy. Eyespot disease of wheat, formerly treated as *Tapesia* (*Ramulispora* asexual states), was shown to represent a distinct genus *Oculimacula* (*Helgardia* asexual states) (Crous et al. 2003), while Quaedvlieg et al. (2011) determined that *Septoria tritici* blotch, caused by “*Septoria*” *tritici*, is in fact better accommodated in a new genus, *Zymoseptoria*, which appears to be restricted to members of Poaceae. The present study also resolved the phylogenetic position of *Septoria nodorum* blotch, which proved to not represent a member of *Septoria*, *Stagonospora*, or *Phaeosphaeria*, but to represent a distinct genus, described here as *Parastagonospora*. Clearly more attention should be directed towards resolving the taxonomy of the pathogens of agricultural crops of major economic importance in future, as these findings also have implications for genomic studies, where organisms from different genera, and even families get compared to one another, and new evolutionary hypotheses are proposed on the assumption that these taxa are congeneric. To clarify the taxonomy of well-known plant pathogens, however, many species will have to be re-collected, and epitypified, so that authentic cultures and DNA barcodes will become available to fix the genetic application of these names.

General conclusions

The genus *Septoria* is defined by having pycnidial to acervular conidiomata, and hyaline conidiophores that give rise to conidiogenous cells that proliferate sympodially and percurrently, forming hyaline, filiform conidia with transverse eusepta. Many species have wide host ranges, and host occurrence should not be used as primary character for identification (see Verkley et al. 2013, this issue). Although species of *Septoria* and several of the novel genera introduced here have mycosphaerella-like sexual states, the name *Mycosphaerella* is restricted to the genus *Ramularia*, and is unavailable for species of *Septoria* and related genera.

ACKNOWLEDGEMENTS

We thank the technical staff, Arien van Iperen (cultures), and Marjan Vermaas (photographic plates), for their invaluable assistance. The research leading to these results has received funding from the European Community's Seventh Framework Program (FP7/2007–2013)/grant agreement no. 226482 (Project: QBOL - Development of a new diagnostic tool using DNA barcoding to identify quarantine organisms in support of plant health) by the European Commission under the theme “Development of new diagnostic methods in support of Plant Health policy” (no. KBBE-2008-1-4-01). Special thanks also go to Dr Ellen van Agtmael who prepared the line drawings included in this paper from photomicrographs and published materials (Sutton 1980) using Adobe Photoshop CS3.
